

CHAPTER II

HISTORICAL

The chemistry of the Genus Artocarpus

Chemical constituents isolated from the genus Artocarpus were reported as steroid, flavonoid, flavonol glycoside, triterpene, xanthone, proteid, lipid. List of the compounds founds in various part of *Artocarpus* spp. are shown in Table 1.

Table 1 Chemical compounds from *Artocarpus* spp.

Plant and chemical compound	category	Plant part	Reference
<i>A. incisa</i>			
Butyric acid, β -amino	Proteid	leaf	Darand et al.1962

THE FLAVONOID

The flavonoids have been known as natural plant products that are not poisons and as dietary ingredients. In 1936 a group of flavonoids is claimed for vitamin P but unfavorable publicity because of undoubtedly medicinal experiment.

At present plant flavonoids are interesting as human dietary components, pharmacologic agents and having significant activity in a variety of isolated animal cell system.

Table 2 The pharmacological activity of flavonoid.

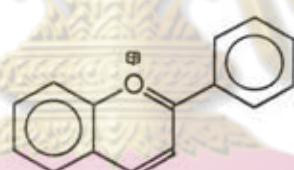

Activitys	Flavonoids	Actions
Antibiotic	anthocyanin and leucoanthocyanin	-inhibit <u>Salmonella</u> , <u>Lactobacillus</u> . <u>Shigella</u> , <u>Proteus vulgaris</u> . <u>Aerobacter aerogenes</u> , <u>E.coli</u> . <u>Staphylococcus aureus</u> .
Antimalignancy	eupatin and centaureidin	inhibit carcinoma from nasopharynx
Antivirus	Concentrate anthocya- nin, flavone,quercetin	inhibit tobacco mosaic virus, inhibit viral replication, inhibit virus in Hela cells
Circulatory activity	flavone, flavonol chalcone, catecin isoflavone,flavandiol	Treatment of Varicose veins, Haemorrhoids, Hypertension,Thrombosis Atherosclerosis

Table 2 continued

Activitys	Flavonoids	Actions
Oestrogen	genistein	Unfertile in lamp (clover disease)
Anti-inflammatory		inhibit pathway of arachidonic acid
Anti-allergic	flavone	inhibit allergic mediator release from mast cell and basophiles

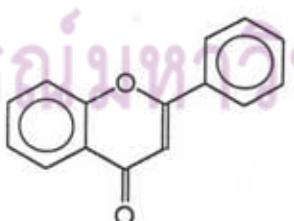

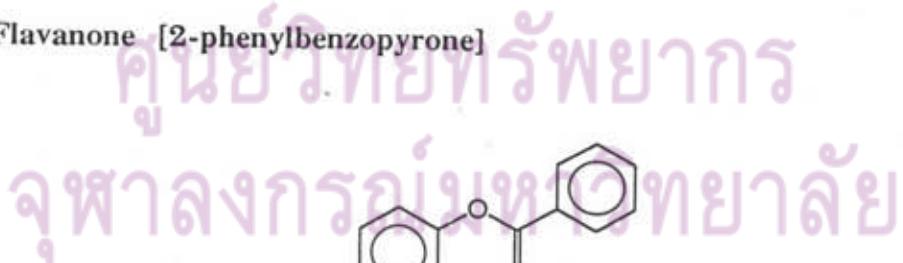

The flavonoids are classified into groups as:-

1. Anthocyanidin [flavylium-2-phenyl benzopyrylium)ion]

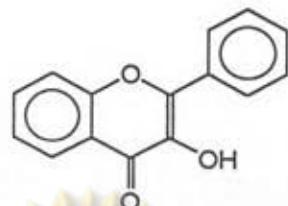

2. Flavanone and Flavanol

2.1 Flavanone [2-phenylbenzopyrone]

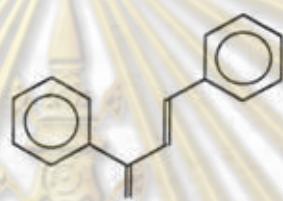

2.2 Flavanol [3-hydroxyflavone]

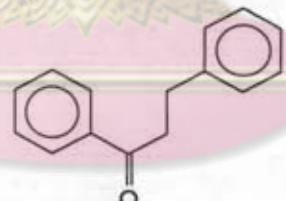

3. Chalcone and Dihydrochalcone

3.1 Chalcone

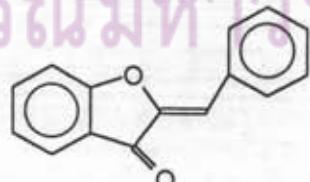

3.2 Dihydrochalcone

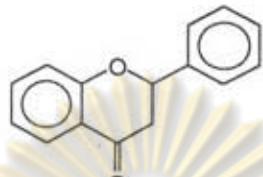

4. Aurone [benzylidencoumaranone]

Biosynthesis of Flavonoid

The flavonoid evolution rests, as in case of other secondary product. It is generally expected that compound which require many steps for synthesis should not be present in the more primitive organisms. The first advantage of flavonoid evolution is potent antioxidant and metal chelator. They reduce the activity of the dangerous oxidant inducing metal such as iron and copper. Second, flavonoid are conjugated aromatic compounds. So they can act both as potent screens against destructive UV light and as attenuators of physiologically active visible light (especially in the 350-450nm. region). Third, they interfere with viral, bacterial, fungal reproduction, growth and development. Finally, they (especially the lignins) can play a role in strengthening the structure of plant cell walls.

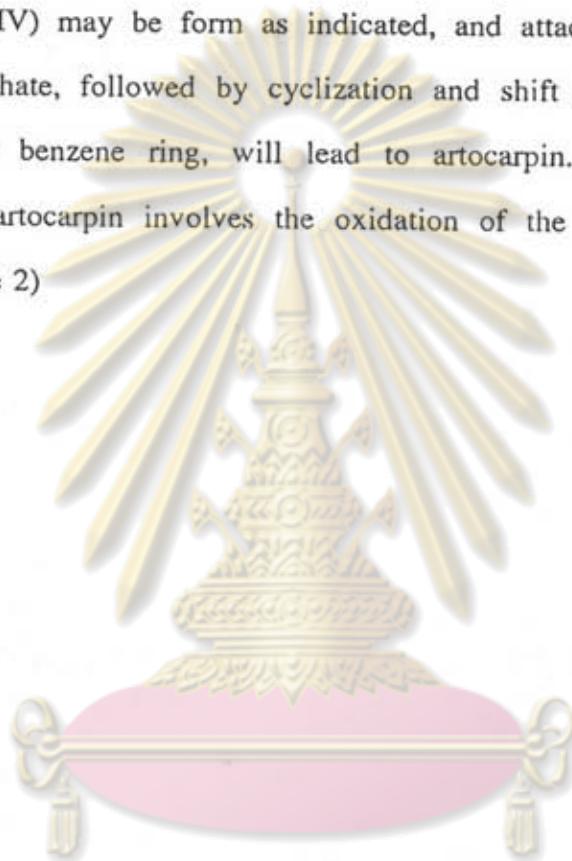

The biosynthesis of flavonoid and related compounds start in the deamination of phenylalanine, require no co-factor, lead to the formation of trans-cinnamic acid. Only the vascular plants, this is a key reaction to synthesize lignins and lignans by transforming cinnamic acid to cinnamoyl alcohol and then polymerizing the latter to the random 3-dimensional structure. The key intermediate for flavonoid formation is the activation of cinnamic acid to p-coumaryl co-A. The reaction of p-coumaryl co-A with three malonic acid via a modified non-reductive fatty acid type biosynthesis give primary product "naringenin" chalcone. The cyclization of naringenin chalcone give flavanone, naringenin. From naringenin, the dehydrogenation of C2-C3 bond in flavanone leads to the flavone, apigenin, and isoflavone. The introduction of a hydroxyl group in the C3 position of naringenin from dihydrokaemferol, flavanonol elaborate flavonol, anthocyanidin, flavan-3ol

(catechins) and flavan-3,4-diols. The latter two groups are being considered as the precursors of condense tannin (proanthocyanidins). (see scheme 1)

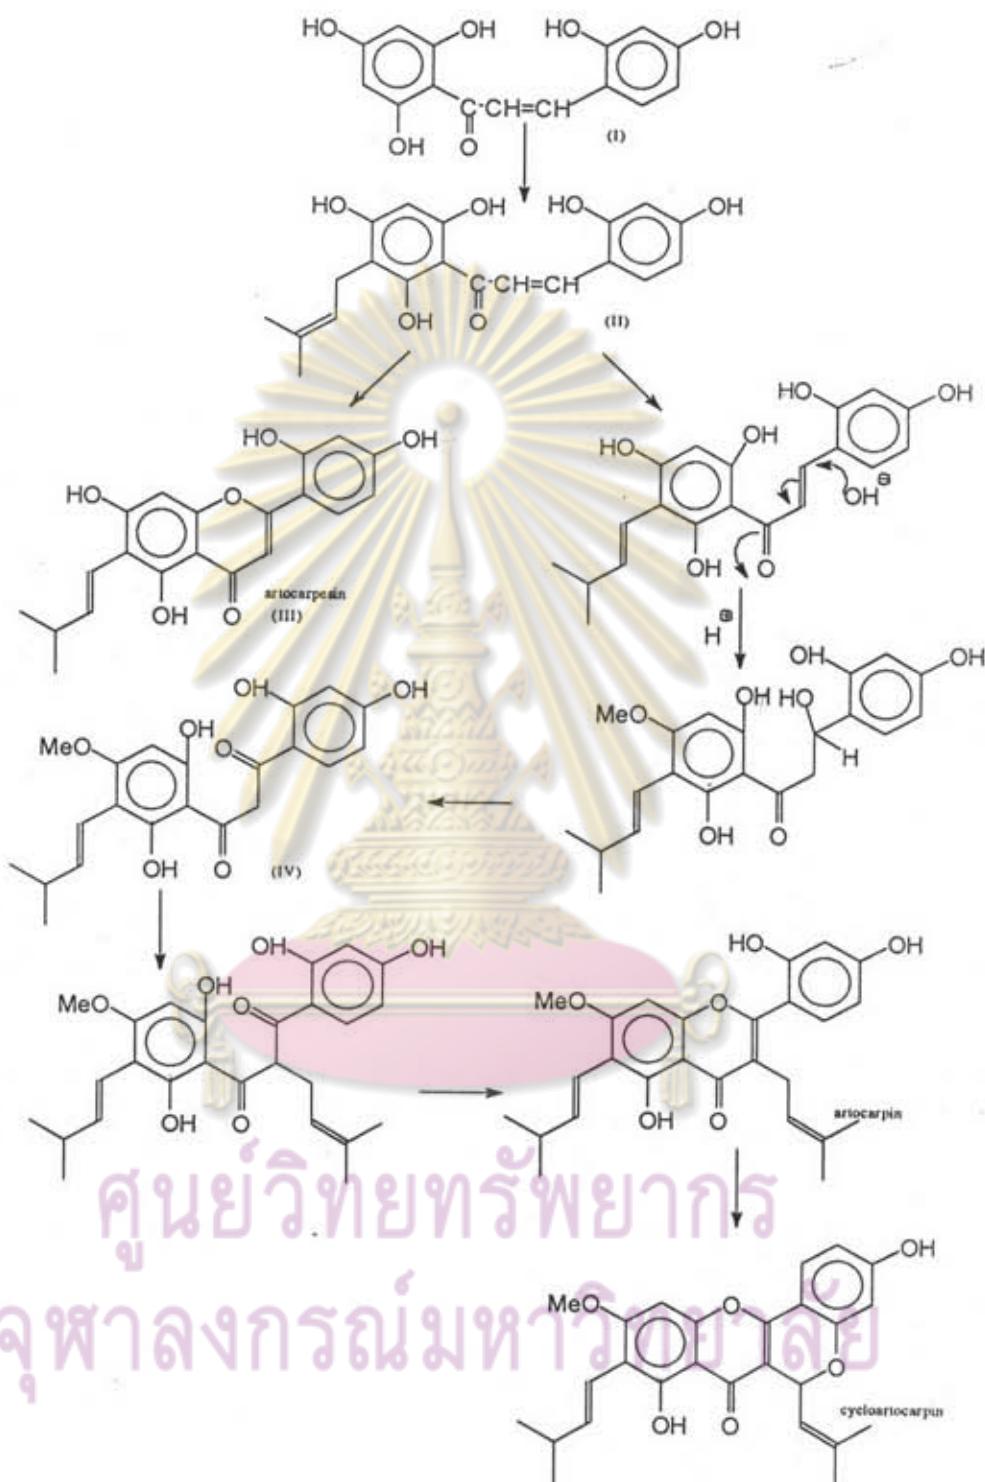

Scheme 1

The biosynthesis of *Artocarpus* flavonoids (Radhakrishnan, Rama Rao and Venkataraman, 1965) start from 2,4-dihydroxy trans- cinnamic acid condenses with acetate-malonate unit to form the chalcone (I). Attack of phoroglucinol nucleus by one unit of 3,3-dimethylallyl pyrophosphate lead to (II) and artocarpesin (III). The dibenzoylmethane (IV) may be form as indicated, and attack by a second unit of dimethylallyl phosphate, followed by cyclization and shift of an olefinic bond to conjugate with the benzene ring, will lead to artocarpin. Further cyclization of artocarpin to cycloartocarpin involves the oxidation of the doubly allylic CH₂ to CHOH. (see Scheme 2)

The Stilbene

Most of stilbene occur in woods. They are fungicidal. The distribution of natural stilbenes are in Pinaceae, Liliaceae, Myrtaceae, Leguminosae, Moraceae, Polygonaceae and Saxifragaceae (Erdtman,1963). The hydroxylation patterns of natural stilbenes and dihydrostilbenes are shown in Table 3.(Venkataraman,1972)

Table 3 Hydroxylation patterns in natural stilbene

(include methyl ether and glucosides)

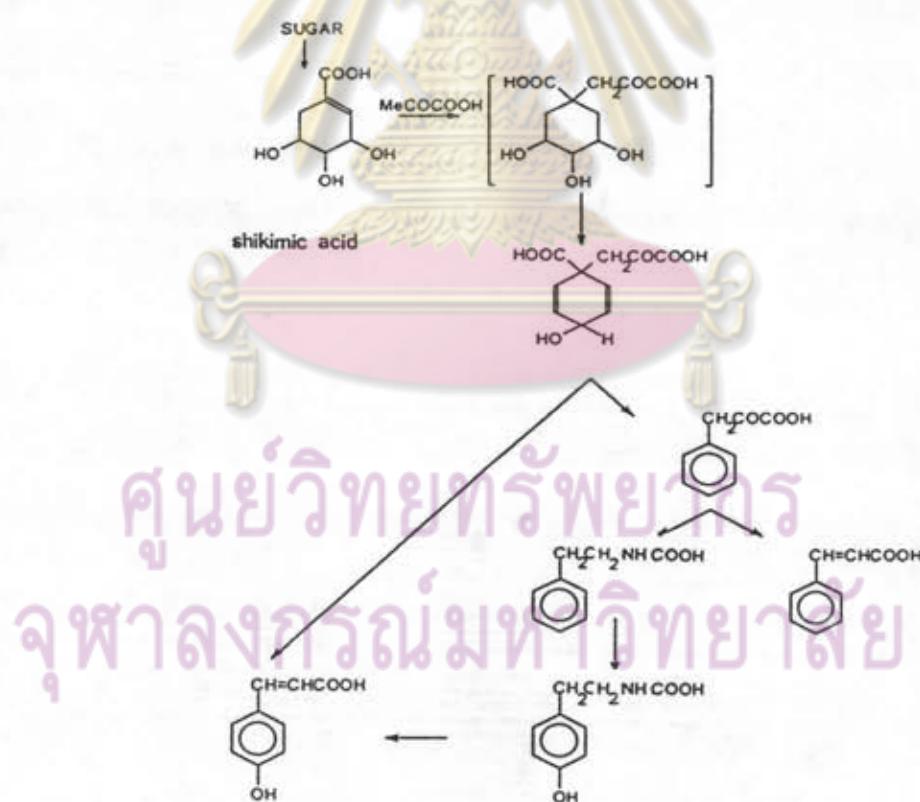

Compounds	Occurance
Stilbene	
4-OH	Pinaceae
3,5-(OH) ₂	Pinaceae,Fagaceae
3,5,4'-(OH) ₃	Pinaceae,Leguminosae,Myrtaceae, Moraceae,Fagaceae,Liliaceae
3,5,2',4'-(OH) ₄	Moraceae (also 4-geranyl),Liliaceae
3,5,3',4'-(OH) ₄	Pinaceae,Leguminosae,Myrtaceae, Moraceae,Polygonaceae
3,5,3',4',5'-(OH) ₅	Leguminosae,Myrtaceae
3,4'-(OH)-2-COOH	Saxifragaceae
Dihydrostilbene	
3,5-(OH) ₂	Detect in 7 pinus species methyl isolated from one
3,5,3',4'-(OH) ₄	Piceae <i>excelsa</i> Link bark
3,4'-(OH) ₂	

Table 3 continued

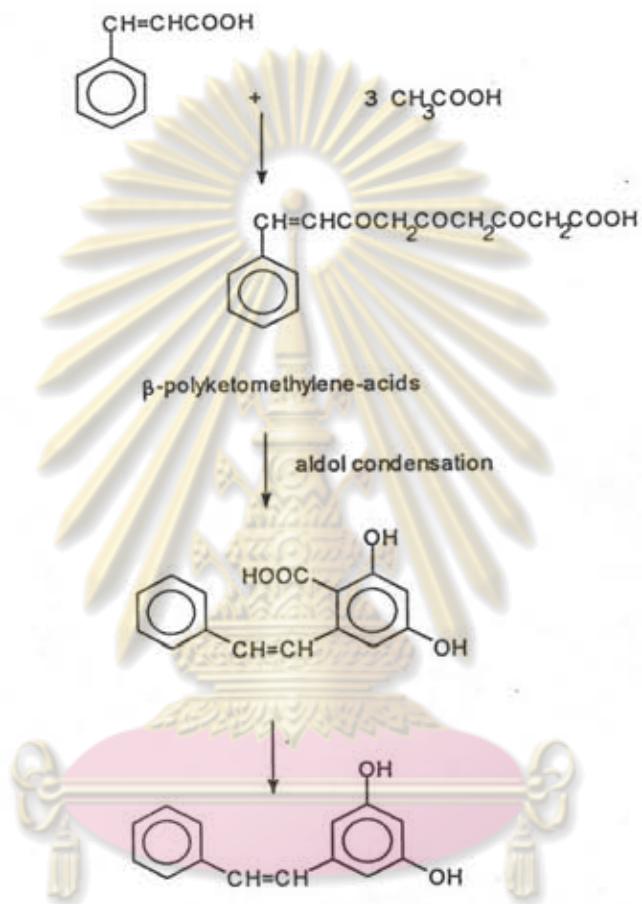

compounds	occurrence
3,2',4'-(OH) ₃	4 Morus species
3,5,2',4'-(OH) ₄	

Biosynthesis of stilbene

The two major biosynthesis routes leading to aromatic compounds are established, one based on shikimic acid, the other on head-to-tail linkage of acetic acid units. The stilbene derivatives that derived from acetic acid are shown in scheme 3 and 4 (Rickards, 1961 and Birch, 1962).
