APPENDICES

Appendix A Investigation of Characteristic Peaks of FT-IR Spectrum of Undoped and Doped Poly(*p*-phenylene)

FT-IR spectrometer (Nicolet/Nexus 670) was used to characterize functional groups of undoped and doped poly(*p*-phenylene) at 50:1 mole ratio of dopant to monomer unit (uPPP and 50:1 dPPP) and operated in the absorption mode in a wavenumber range of 4000-400 cm^{-1} with 32 scans and $\pm 4 \text{ cm}^{-1}$ resolution. Optical grade potassium bromide (KBr) was used as a background material and dried before being mixed with PPP at a ratio of 20:1.

Figure A1 The FT-IR spectra of uPPP and 50:1 dPPP.

The FT-IR spectrum of PPP synthesized by Kovacic's direct route (Kovacic *et al.*, 1963) through oxidative cationic polymerization was shown in Figure A-1. The characteristic absorption peak situated at 805 cm^{-1} was corresponding to *para* aromatic substitution. The less intense absorption peaks occurred at 763 and 695 cm^{-1} were assignable to mono substitution of benzene rings. Moreover, there were additional bands of secondary intensity of *para* band located at 999 , 1396 , and 1479 cm^{-1} (Kovacic *et al.*, 1963). The several precise assignments of characteristic FT-IR spectrum for PPP were summarized in Table A-1 (Kvarnstrom *et al.*, 1997; Lacaze *et al.* 1997).

The doping of PPP caused the occurrence of new absorption peaks at 1545 and 1180 cm^{-1} that were not appeared in the undoped state of PPP. The doping induced IR characteristic peaks were not due to specific vibrations of dopant molecules or between the molecules and the polymer chain, because the similar peaks appeared for K-, AsF_5 - and FeCl_3 -doping, therefore they are intrinsic vibration of the polymer chain in doping state (Yli-Lahti *et al.*, 1985; Shacklette *et al.*, 1980; Yaniger *et al.*, 1984).

Table A1 Typical IR assignments of uPPP

Wavenumber (cm^{-1})	Characteristic bands	References
3026 ± 0.6 [3029]	C-H stretching of aromatic	Dale, 1957 and Castiglioni <i>et al.</i> , 1989

1396 ± 2.0 , 1479 ± 0.4 [1390, 1480]	C-C stretching of aromatic	Pham <i>et al.</i> , 1990
999 ± 0.5 , 1250 ± 4.0 [1000, 1255]	C-H in-plane vibration of <i>para</i> disubstituted phenyl rings	Soubiran <i>et al.</i> , 1998
805 ± 0.6 [817-805]	C-H out of plane vibration of <i>para</i> disubstituted phenyl rings	Froyer <i>et al.</i> , 1985
763 ± 2.0 [760]	C-H out of plane vibration mono substituted phenyl rings	Kvarnstrom <i>et al.</i> 1985
695 ± 1.0 [692]	C-H out of plane vibration of mono substituted phenyl rings	Rakovic <i>et al.</i> , 1991

Appendix B Thermal Property of uPPP and 50:1 dPPP

The thermal property of uPPP and 50:1 dPPP was examined by a thermal gravimetric technique. Thermal Gravimetric Analyzer (duPont/TGA 2950) was used in operating mode: heating rate of 10 °C/min and temperature scan from 30-800 °C under air atmosphere. There was single transition step of both uPPP and dPPP decomposition under air atmosphere. Single transition of uPPP and dPPP decomposition under air atmosphere was noticed as shown in Figure B-1. It was obviously observed that uPPP is thermally and thermooxidatively stable. There was no significant decomposition appeared below 400 °C. It meant that at temperature up to 400 °C uPPP demonstrated good resistance to thermal degradation and air oxidation (Kovacic *et al.*, 1963). At approximately 569 °C PPP backbone began to decompose responsible for the loss of benzene.

dPPP proposed less thermal stability with gradually decomposed when temperature increased, than the undoped one, because doping induced the defect in the polymer chain. However, dPPP still withstand the heat until most of dPPP molecule decomposed at around 480 °C. Moreover, after decomposition dPPP had higher amount of residue than uPPP due to the addition of ferric chloride dopant.

Figure B1 TGA thermogram of uPPP and 50:1 dPPP.

Table B1 Decomposition of uPPP and 50:1 dPPP

Sample	T_d (°C)	% Weight loss	% Residue
uPPP	569±4	98.04±0.83	1.96±0.83
50:1 dPPP	480±6	86.95±1.10	13.05±1.10

Appendix C Identification of Crystallinity of uPPP and 50:1 dPPP and Structure of Zeolite

X-ray Diffractometer (Phillips, Rigaku) was used in order to identify the crystallinity of uPPP and 50:1 dPPP and ensure the structure of zeolite. Both uPPP and dPPP powder were compressed into pellet form with 10 mm in diameter and 0.15-0.25 mm in thickness. Zeolite powder was packed into a glass plate. The XRD patterns showed that uPPP had quite high crystalline accompanying with the d -spacing value of 4.53, 3.63 and 3.24 Å. The most intense d -spacing was 4.53 Å which closely corresponded to the length of a phenyl unit (Kovacic *et al.*, 1963; Marvel *et al.*, 1959). Therefore, it was postulated that the rings were very nearly coplanar. However, the pattern of uPPP did show the existence of some amorphous regions.

Some peaks presenting in the uPPP pattern were disappeared or reduced in intensity after doping with FeCl₃ which meant FeCl₃ dopant can decrease the crystallinity of PPP. It might be due to the distortion of the polymer chain after being doped.

By using XRD technique, the structure and crystallinity ZSM-5 was confirmed. XRD patterns and peak positions matched those observed for the characteristic structure of MFI. The peak intensities and low background lines demonstrated the high crystallinity of the sample.

Figure C1 XRD pattern of uPPP and 50:1 dPPP.

Figure C2 XRD pattern of ZSM-5 with SiO₂/Al₂O₃ of 23.

Appendix D Determination of Particle Size and Particle Size Distribution of PPP and Zeolite Powder

Particle Size Analyser (Malvern/Mastersizer X Version 2.15) was employed to examine the particle size and particle size distribution of materials. Synthesized PPP was ground and subsequently sieved with 54 μm sieve before being analyzed.

Table D1 Mean particle diameter of materials

Materials	Mean particle diameter (μm)				
	1	2	3	Avg.	SD
PPP	33.74	33.41	33.69	33.61	0.18
ZSM-5(23)	5.46	5.45	5.47	5.46	0.01

Appendix E Density Measurement

Density of PPP and zeolite can be measured by using pycnometer at controlled temperature. Blank pycnometer was firstly weighed and then water was added into the pycnometer and weight of pycnometer with water was measured again. The density of water can be calculated through equation (E1)

$$\rho_w = \frac{(a-b)}{25} \quad (\text{E1})$$

where ρ_w is the density of water (g.cm^{-3}), a is the weight of pycnometer with water (g), b is the weight of blank pycnometer (g).

The blank pycnometer was weighed again and then sample powder was introduced into the pycnometer and the total weight was measured. After that the water was added into the same pycnometer and again the total weight was measured. In this step, the volume of added water will be obtained from equation (E2) and finally the density of the sample can be calculated through equation (E3)

$$A = \frac{(e-d)}{\rho_w} \quad (\text{E2})$$

where A is the volume of added water (cm^3), e is the weight of pycnometer with sample and added water (g), d is the weight of pycnometer with sample (g).

$$\rho_m = \frac{(d-b)}{25-A} \quad (\text{E3})$$

where ρ_m is the density of material (g.cm^{-3}).

Table E1 Density of materials

Materials	Density(g.cm^{-3})
PPP	1.3273±0.0011
ZSM-5(23)	1.9739±0.0004

Appendix F Morphology

Scanning Electron Microscope (SEM) (JEOL/JSM 5200) was utilized to examine the morphology of materials. Samples were coated with gold before being characterized in order to suppress the charge up phenomena. The morphology of PPP (Figure F-1) shows rough surface and irregular shapes.

Appendix G Identification of Si/Al and Cation Exchange Level of Zeolite

An Atomic Absorption Spectrometer (AAS) (Varian/SpectrAA 300) was used to determine the amount of Si and Al containing in zeolite and the amount of desired cation after ion exchange processes. The known weight zeolite was dissolved with hydrofluoric acid (HF) and hydrochloric acid (HCl). After the volume of solution was adjusted, the solution was filtered before being tested. Standard, blank and sample solutions were prepared for testing of each cation and different lamps were used for different cations.

The Si/Al ratio of zeolite can be calculated via equation (G1)

$$Si / Al \text{ ratio} = \frac{\text{mole of Si / g of zeolite}}{\text{mole of Al / g of zeolite}} \quad (G1)$$

Table G1 Si/Al ratios of zeolite

Zeolite	Cation content (mole/g zeolite)		Si/Al
	Si	Al	
ZSM-5(23)	1.3849×10^{-2}	1.0930×10^{-3}	12.67

Before performing cation exchange process, ZSM-5 zeolite contains the NH_4^+ cation. After the process, cation containing in the ZSM-5 was changed and the actual amount of balancing cation was then determined. Cation exchange level can be calculated on the assumption that 100% cation exchange possesses identical mole number of incoming cation and Al as followed equation (G-2)

$$\text{Cation exchange level} = \frac{\text{mole of cation / g of zeolite}}{\text{mole of Al / g of zeolite}} \quad (G-2)$$

Table G2 The cation exchange level of $\text{NH}_4\text{ZSM-5(23)}$ with Na^+ and K^+

Sample	Cation	Times	$[\text{Al}_3^+]$ (mmol/g zeolite)	[cation] (mmol/g zeolite)	% Exchange
ZSM-5(23)	Na^+	1 st	1.0978	1.0674	97.23
	K^+	1 st	1.0978	1.0576	96.34

Appendix H Surface Area and Pore Volume of Zeolite

Surface area and pore volume of zeolite were determined by employing a Surface Area Analyzer (SAA) (Quantachrome/Autosorb-1). Dried zeolite was weighed and out gassed at 250 °C over night before being performed adsorption and desorption with He and N₂ gases.

Table H1 Surface area and pore volume of zeolite

Zeolite	BET Surface area (m ² /g)	Pore volume (cm ³ /g)
NH ₄ ZSM-5(23)	290.1±0.85	0.1819±0.0031
HZSM-5(23)	332.6±6.51	0.2075±0.0006
NaZSM-5(23)	283.1±8.63	0.1759±0.0112
KZSM-5(23)	273.3±1.34	0.1663±0.0074

It was well-known that if the zeolite contains different cation, the surface area and pore volume of the zeolite are also different due to the various types of cation whose size of cation are not the same. From table G-1, the surface area and pore volume of ammonium cation form existing in ZSM-5 are 290.1m²/g and 0.1819 cm³/g, respectively. After calcination without passing cation exchanged process, ammonium cation became H⁺ because of the removal of NH₃ during calcination process, therefore the surface are and pore volume of zeolite increase up to 332.6 m²/g and 0.2075 cm³/g, respectively. Due to K⁺ possesses the larger cation size than Na⁺, thus ZSM-5 containing K⁺ have less surface area and pore volume than NaZSM-5.

Appendix I Correction Factor (K) Measurement

A two point probe meter connected with a source power supplier (Keithley/ Model 6517A) was employed to determine the electrical conductivity of materials. A constant voltage is applied and a current is simultaneously measured.

According to the geometric effects of the probe, the geometrical correction factor was taken, depending on the configuration and probe tip spacing

$$K = \frac{w}{l} \quad (11)$$

where K is geometric correction factor, w is width of probe tip spacing (cm), l is length between probes (cm).

The constant K can be determined by using standard materials whose specific resistivity values are known. In our case, silicon wafer chips were used as the standard materials. The resistance was measured by using our custom made two-point probe, obtained by applying various voltages and simultaneously measuring currents. The geometric correction factor was calculated via equation (12)

$$K = \frac{\rho}{R \times t} = \frac{I \times \rho}{V \times t} \quad (12)$$

where ρ is resistivity of standard silicon wafer ($\Omega \cdot \text{cm}$), which was calibrated by using four point probe at Thailand Microelectronic Centre (TMEC), R is resistance of film (Ω), t is film thickness (cm), I is measured current (A) and V is applied voltage (V).

Table II The correction factor of several two point probes.

Appendix J Conductivity Measurement

The electrical conductivity (σ) can be measured by using the two-point probe meter connected with a voltage supplier (Keithley, 6517A) which its constant voltage can be changed and the current is reported. The conductivity measurement was performed under atmospheric pressure, 40-60% RH and at 25-27 °C. The responsive current linearly proportional to the applied voltage is called the linear ohmic regime which can be identified by plotting the applied voltage against with the current. The voltage and the current in the regime were converted to the electrical conductivity by following equation (J1)

$$\sigma = \frac{1}{\rho} = \frac{1}{R_s \times t} = \frac{I}{K \times V \times t} \quad (\text{J1})$$

where σ is specific conductivity (S/cm), ρ is specific resistivity ($\Omega \cdot \text{cm}$), R_s is sheet resistance (Ω/sq), t is thickness of sample pellet (cm), V is applied voltage (voltage drop) (V), I is measured current (A), and K is geometric correction factor of the two-point probe meter.

In this measurement, the probe 2 was used; whose K is 4.205×10^{-5} and the thickness of the samples was measured by using a thickness gauge.

Table J1 The specific conductivity (S/cm) of uPPP, dPPP with various doping level and NaZSM-5(23) zeolite

Appendix K Electrical Conductivity Sensitivity Measurement

The electrical conductivity of dPPP and dPPP/zeolite composite pellets under both N₂ and NH₃ gas atmosphere were carried out by using two point probe, under pressure 1 atm, at 29±1 °C. The electrical conductivity response of the sample is defined as the difference between the equilibrium conductivity of sample under exposed to NH₃ and that of samples under N₂ exposure.

$$\Delta\sigma = \sigma_{NH_3} - \sigma_{N_2 \text{ initial}} \quad (\text{K1})$$

The electrical conductivity sensitivity is calculated from the electrical conductivity response divided by equilibrium conductivity under exposed to N₂.

$$\text{Sensitivity} = \Delta\sigma / \sigma_{N_2 \text{ initial}} \quad (\text{K2})$$

Appendix L Ammonia Temperature Programmed Desorption

An ammonia temperature programmed desorption (NH₃-TPD) of zeolite was performed in a flow-through reactor with helium as a carrier. In order to remove water and undesired impurities, approximated 0.05 g of sample was pre-treated under He flow by heating from 30 °C to 500 °C at 10 °C/min. After holding temperature at 500 °C for 1 h and cooling to ambient temperature, the gas flow was switched to 1% NH₃/He. The NH₃ adsorption under room temperature was allowed for 1 h and the removal of weakly adsorbed NH₃ was then achieved by purging He gas into the system for 2 h. The NH₃ desorption was done by elevating temperature from 30 °C to 600 °C at ramp rate of 10 °C/min. In case of dPPP, NH₃ desorption was performed by elevating temperature from 30 °C to 300 °C. The desorbed NH₃ was detected by thermal conductivity detector (TCD).

Figure L1 NH₃-TPD thermogram of ZSM-5(23) with various cation types.

Figure L2 NH₃-TPD thermogram of 50:1 dPPP.

Appendix M Investigation of Interaction between dPPP, dPPP composite, NaZSM-5(23) and NH₃ by using FTIR technique

FTIR spectra of 50:1 dPPP, 50:1dPPP(70)/NaZ23 and NaZSM-5(23) were taken by using KBr pellet technique. The sample pellet was located on sample holder and put in the gas cell. The spectra of samples were collected, before, during and after NH₃ exposure, in order to study the interaction between these samples and NH₃.

Figure M1 The FT-IR spectra of 50:1dPPP; before, during and after NH₃ exposure.

Figure M2 The FT-IR spectra of 50:1dPPP(70)/NaZ23; before, during and after NH_3 exposure.

Figure M3 The FT-IR spectra of NaZSM-5(23); before, during and after NH_3 exposure.

Figure M4 The FT-IR spectra of 50:1dPPP versus time of NH₃ exposure.

Figure M5 The FT-IR spectra of NaZSM-5(23) versus time of NH₃ exposure.

Figure M6 The FT-IR spectra of 50:1dPPP(70)/NaZ23 versus time of NH_3 exposure.
