SAMPLES OF CALCULATION

In this part, the method of processing the data obtained from radioactive tracer method is illustrated. The data obtained comprise of a number of channels registered the radiation counts and radiation counts. Data obtained from both batch mixing and continuous mixing experiment were processed. Some of them are shown in Table A.1 for batch mixing experiment and in Table A.2 for continuous flow experiment.

The following is a brife explanation how those data were processed.

A.1 Data Preprocessing

For both batch mixing and continuous flow experiment all data were preprocessed as follows:

- A.1.1 The registered channel and radiation counts were transfered to a computable programme (column A and column D respectively). In this work, Symphony release 2.0 was used.
- A.1.2 The channels was converted to time (column B). Because the counting time was set at 0.5 second, so one channel increment corresponds to 0.5 second. And the time of injection was set to be zero (cell B1).
- A.1.3 The middle time of each counting interval were selected to represent the time after injection (column C).

A.1.4 The mean value of a set of one hundred data of the radiation counts before the time of injection (these data were not shown here) was computed (cell D1) to represent the background radiation.

A.1.5 The radiation counts after the time of injection were corrected by both background corection to obtain net counts (column E), and decay correction (column F) to bring them back to the time of injection. For background correction, the counts was subtracted by the background. The decay correction was computed by using decay equation in Eq. $(A.1)^{(18)}$.

$$A_o = A e^{-\lambda t}$$

$$= 0.693/t_{1/2}$$
(A.1)

where; A_0 = counts at time of injection

A counts at time t after injetion

> decay constant

t = time after injection

 $t_{1/2}$ = hafe-life of radioactive material

A.2 Further data processing for batch mixing

For batch experiment, the preprocessed data were further processed as follows:

A.2.1 The mean and standard deviation of a set of one hundred data after injection 50 second was evalated (cell B206 and B207 recpectively) to set upper and lower limits.

- A.2.2 All data were normalized by dividing with the mean (column G, H and I).
- A.2.3 The upper limit, its mean plus 3 time of its standard deviation (cell B210), and the lower limit, its mean minus 3 time of its standard deviation (cell B 209) were computed. These limit were extended back to the time of injection (column H and I).
- A.2.4 The shortest time that counts at that time and after was not exceed these limits was verified.

For another method of determining, the followings step had been done.

- A.2.5 The standard deviation of a set of one handred data was calculated (column J) by moving average method '20'. The first set of data started from the time of injection (cell F1 to F100). Then the second set of data shifted to the next time, 0.5 second after injection (F2 to F101) and so on.
- A.2.6 The shortest time that the standard deveation at that time and after was fairly constant was verified.

The formular of some cells in Table A.1 are shown below:

Cell	Formular
A25	+A24+1
B25	+B24+0.5
C25	+(B24+B25)/2

B206	@AVG(F104F203)
B207	@STD(F104F203)
B208	+B206-3*B207
B209	+B206+3*B207

A.3 Further data processing for continuous flow

For continuous mixing experiment, the preprocessed data were further processed as follows:

A.3.1 The \cdot corrected counts were normalized by diviidng with the maximum counts(column G).

A.3.2 The the product of time, normalized corrected counts at that time and counting time interval was calculated (column H) starting from the time of injection.

A.3.3 The product of normalized corrected count and counting time interval was calculated (column I).

A.3.4 The residence time was calculated (D250) Using Eq. (A.2) $^{(21)}$ (by dividing the sum of product obtained in (A.3.2) by the product obtained in (A.3.3).

$$t = \int \frac{c \cdot t dt}{c dt}$$
 (A.2)

where; C = normalized corrected counts

t = time

dt = counting time interval

AUTOBIOGRAPHY

Pipop Thamtharai was born on January 27, 1958 in Bangkok, Thailand. He received his Bachelor of Science Degree in Chemical Engineering from Chulalongkorn University, Bangkok, Thailand, in 1980. He has worked at Office of Atomic Energy for Peace, Ministry of Science Technology and Energy since 1980.
