## 6172120223 : MAJOR CHEMISTRY

KEYWORD: MEMBRANE PROTEIN, VOLTAGE-SENSING DOMAIN, NITROXIDE SPIN LABEL, SPIN LABELING, MD SIMULATIONS

Ngoc-lan Le-nguyen : STRUCTURE AND DYNAMICS OF SPIN LABEL SIDE CHAINS IN MEMBRANE PROTEIN USING MOLECULAR DYNAMICS SIMULATIONS. Advisor: Prof. PORNTHEP SOMPORNPIST, Ph.D.

Site-directed spin labeling (SDSL) combined with electron paramagnetic resonance (EPR) spectroscopy is a powerful approach to explore the structure and dynamics of biological complex systems. Nitroxide spin label is the most widely used probe for SDSL in the study of structure and function of biomolecules. However, the behavior of the nitroxide spin label is not well understood. This study aims to characterize the structural and dynamical properties of the spin label in the voltage-sensing domain (VSD) of KvAP, a potassium channel from the thermophilic archaea *Aeropyrum pernix* by mean of molecular dynamics (MD) studies. MD simulations for unlabeled and a total of 132 spin labeled KvAP-VSD models (on attachment for the residue position from 20 to 151) were carried out in a phospholipid bilayer to evaluate the dynamics of the nitroxide spin label side chain in membrane proteins. Structural flexibility, conformational freedom of rotatable bonds, and orientation of the nitroxide side chain were investigated in relation to the spin label internal motion in different microenvironments. The analysis of MD data showed that the backbone dynamics between the unlabeled and spin-labeled proteins were similar. The conformational freedoms of the nitroxide side chain vary with the surrounding environments. The spin label motion is more restricted inside the membrane than the outside membrane. From the simulations, the rotatable bonds within the nitroxide side chain adopt distinct values of dihedral angles indicating different dynamics of the spin label in different environments. The radial distribution function plots between the spin label and the nearest-neighbor surroundings allow to categorize the spin labels into water exposure, lipid-exposure, and protein burial. The dynamics of the spin label side-chains decreases in the following order: water-exposed > lipid-exposed > buried type. The MD results were compared with available experimental EPR data. The study provides a detailed understanding of the structure, conformation, and dynamics of the spin label.

## ACKNOWLEDGEMENTS

Foremost, I would like to express my sincere gratitude to my advisor Prof. Dr. Pornthep Sompornpisut for the continuous support of my study and research, for his patience, motivation, thoughtfulness, and immense knowledge. His guidance helped me in all the time of research and writing of this thesis. Besides my advisor, I would like to thank the rest of my thesis committee: Assoc. Prof. Dr. Vudhichai Parasuk, Assoc. Prof. Dr. Somsak Pianwanit, and Asst. Pr of. Dr. Chalernpol Kanchanawarin for their encouragement, insightful comments, and suggestions. Moreover, I also would like to thank the lecturers from the Department of Chemistry, Faculty of Science, Chulalongkorn University for giving me useful knowledge during my Master's degree.

My sincere thanks also go to my seniors: Ms. Warin Rangubpit, Mr. Panyakorn Taweechat, Mr. Channarong Khрутto, Mr. Pavee Apilardmongkol, Mr. Thanawit Kuamit, Mr. Tawatchai Jitporn, and Mr. Fadjar Mulya as well as other members in the computational chemistry unit cell (CCUC) at Department of Chemistry, Faculty of Science, Chulalongkorn University for their support, discussion, encouragement, and cheerfulness.

In addition, I would like to acknowledge all my financial supports including the Graduate Scholarship Program for ASEAN Countries and the 90th Anniversary of Chulalongkorn University Scholarship from Chulalongkorn University.

Last but not least, I would like to thank my family and friends for being beside and supporting me all the time.

Ngoc-lan Le-nguyen

# Chapter 1

## INTRODUCTION

### 1.1 Membrane protein

Cell membranes are essentially constituted by membrane lipids and membrane proteins in the presence of a certain amount of carbohydrates as shown in Figure 1.1. Membrane proteins (MPs) are observed much more structurally and functionally diverse than membrane lipids. They have important functional roles involved in ion and molecule conduction, energy transduction, cell integrity, and cell-cell interactions.

#### Extracellular

#### Intracellular

**Figure 1.1** Schematic diagram of some typical membrane proteins in a cell membrane

However, MPs are complicated to analyze in their native body cells, due to their embedding in the membrane lipids. In particular, the crystallization process of MPs has been nontrivial and elusive, owing to the difficulties when overexpressing them in bacteria and denaturation when removing from their native environment. Their poor water solubility has hampered the crystallization – an essential stage in X-ray crystallography. That imposes the presence of detergents to render membrane proteins water-soluble. However, there is no universal detergent that works for all membrane proteins. More importantly, they can also alter conformation and function of membrane proteins since they hinder inter- and intra-molecular protein-detergent interactions. Taken together, these aspects lead to the difficulties of experimental techniques in characterizing the MPs structure. Although one third of the coded protein in the human genome

encodes membrane proteins, it has been found around 1-2% of the total available structures in the Protein Data Bank (PDB) systematically elucidated (1). Moreover, roughly over 50% of all FDA approved medicinal drugs target membrane proteins (2,3).

**Figure 1.2** Schematic diagram of voltage-gated ion channel (a) specified by individual ions and (b) typical structure with six segments (S1-S6) including voltage-sensing domain (VSD, S1-S4)

Ion channels are the primary target for the drug development. They are responsible for a variety of physiological functions such as neural transmission, cell signaling, regulation and transduction etc. There are different types of ion channels: voltage-gated ion channels, ligand-gated ion channels, mechanically-gated ion channels, and some leak channels. Voltage-gated ion channels are the largest superfamily of ion channels. They comprise primarily of potassium  $K^+$ , sodium  $Na^+$ , and calcium  $Ca^{2+}$  channels as represented in Figure 1.2a. Ion channels of this class share common structural features including a canonical voltage-sensing domain (VSD) and pore

domain (PD) as shown in Figure 1.2b. The VSD plays a crucial role during voltage activation. The PD is important for the selectivity, permeation and gating for ions.

## 1.2 Site-directed spin labeling EPR technique

A spin label (SL) agent is a probe molecule that is typically used in spectroscopic study as well as biochemical assay. It contains an unpaired electron. The SL agent can selectively bind to molecules containing a specific function group. Spin labels together with electron paramagnetic resonance (EPR) spectroscopy are commonly employed as external molecules for monitoring local dynamics of protein or biological membranes. Site-directed spin labeling (SDSL) combined with EPR has become a powerful technique allowing us to probe structure and dynamics of particular areas within a protein, to validate protein-protein and protein-ligand interactions, and to characterize structural architecture of proteins.

For the attachment of proteins with spin labels, three main approaches have been currently used so far:

- Spin labeling at cysteine position
- Spin labeling by peptide synthesis
- Spin labeling using nonsense suppressor methodology

The first approach is most commonly one that utilizes the reaction of cysteine substitution mutants in the protein. This approach usually requires that the protein contains only cysteine residues at the desired sites. the cysteine can replace amino acid residue at any position along protein sequence without protein functional changes. Spin label side chains are created by a substitution reaction between sulfhydryl group of cysteine side chain and the spin label reagents (4,5). Among different types of spin labels, nitroxides are widely employed. They are very sensitive and provide insights into the polarity, solvent accessibility, and rotational dynamics of specific sites of the protein. The nitroxide spin labels are potential probes for investigating protein dynamics.

**Figure 1.3** Structures of nitroxide spin labels used in the SDSL/EPR study of micromolecules (a) Methanethiosulfonate spin label (MTSSL), (b) maleimide spin label (MSL) N-(1-oxyl-2,2,6,6-tetramethyl-4-piperidinyl) maleimide, (c) iodoacetamide spin label (ISL), (d) bis(1-oxyl-2,2,5,5-tetramethyl-3-imidazolyl) disulfide (IDSL), (e) bifunctional spin label (BSL), (f) 2,2,6,6-tetramethyl-N-oxyl-4-amino-4-carboxylic acid (TOAC), and (g) 4-(3,3,5,5-tetramethyl-2,6-dioxo-4-oxypiperazin-1-yl)-1-phenylglycine (TOPP) (6)

There are several nitroxide spin label probes for SDSL combined with EPR spectroscopic studies of biomolecules (7-14) as shown in Figure 1.3 (6). The spin labels in Figures 1.3(a)–1.3(e) are attached to proteins via site-directed mutagenesis while those in Figures 1.3(f)–1.3(g) are incorporated through peptide synthesis. A resulting side chain established by the reactivity of the most flexible commonly applied spin label, (1-oxyl-2,2,5,5-tetramethylpyrroline-3-methyl) methanethiosulfonate spin label (MTSSL), with the cysteine residue of the protein is introduced in Figure 1.4, commonly abbreviated by R1 side chain.

In this study, the structure and dynamics of spin label side chains at all amino acid positions of the X-ray structure of the voltage-sensing domain (VSD) of a potassium channel from the archeobacterium *Aeropyrum Pernix* (KvAP) (15) were investigated using all-atom molecular

dynamics (MD) simulations. The dynamical properties are compared to the experimentally-determined mobilities obtained from the previously published EPR data (16).

**Figure 1.4** Spin label side-chain (R1) produced by reaction between a cysteine residue and MTSSL

### 1.3 Literature review

#### 1.3.1 Site-directed spin labeling EPR technique for studying membrane proteins

The motion of spin label side-chain is highly dependent on its neighboring side chains and secondary structure constituents in its exposed environment. Therefore, the local structural and dynamical properties of the protein can be reported. A pioneering work of Hubbell and co-workers introduced SDSL EPR technique around 30 years ago (17). Remarkably, one of the first studied proteins was a membrane protein. Since then it has become a commonly complementary tool in structural biology. In the spin labeling procedure, one can intentionally select the location of interest, or scan along the protein sequence seeking for differences along the protein chain. In addition, the relationship between the dynamics of the spin label side-chain and protein structure has been extensively studied for T4 lysozyme (18-22)

Using nitroxide-based site-directed spin labeling (SDSL) EPR, membrane protein topology can be investigated (23,24). Functional domains in membrane proteins can be identified applying this method (18). Moreover, there are some essential MPs have been studied in terms of the structure and dynamic properties such as KCNE1, KcsA, amyloid precursor C99 domain, lactose permease, integrin, bacteriorhodopsin, and KvAP-VSD (16,23,25-30). In the study of KvAP-VSD (16), the structural transition between the “down” and “up” conformations was investigated using SDSL EPR spectroscopic approaches. Spin labels were attached at residues 16–147 on the VSD one at a time in both PCPG and DOTAP liposomes. Then, mobility and solvent accessibility at each site of KvAP-VSD in the liposomes were calculated, applying EPR spectroscopy studies.

The SDSL/EPR approach has been applied to study the structure and dynamics of KCNE1 which plays a vital role in modulating the function of the voltage-gated potassium ion channel ( $K_v$ ) (25,31). The EPR data indicated that the motion of nitroxide spin label side chains attached in the KCNE1 transmembrane domain (TMD) are more restricted than those located in the extracellular area of KCNE1. A study on the amyloid Obr2A is another recent instance of employing nitroxide spin labeling combined with EPR spectroscopy (32). They varied the concentration of lipids to elucidate the spin label side-chain flexibility.

McCaffrey *et al.* employed a bifunctional spin label in combination with EPR spectroscopy at X-band on phospholamban (PLB) which is an integral membrane protein to find the protein structure (33). The results suggested that EPR data of the spin label can be utilized to clarify the direction and dynamics of an integral membrane protein segment in magnetically aligned bicelles. Using that technique and TOAC spin labeling at multiple sites, the correct helical tilt angle and dynamical feature of the AchR M2 $\delta$  peptide was recently determined by the Lorigan group (34).

Besides, SDSL/EPR can be used to estimate distances from within or between the spin labeled sites in MPs. This distance information can be calculated from two spin labels either in the same protein or different proteins (35) based on the magnetic dipolar interactions between their unpaired electrons. These distances can be measured to monitor the secondary, tertiary, and quaternary structure of MPs (36).

### 1.3.2 Computational studies of the nitroxide side chain in membrane protein

The main impact on continuous wave EPR spectra and on nuclear spin relaxation times initiates from fluctuations of dihedral angles  $\chi_1$  to  $\chi_5$  as introduced in Figure 1.5. For the nitroxide spin label MTSSL, the appropriate angles  $\chi_1$  to  $\chi_5$  are shown in Figure 1.6 (37). Depending on these rotational conformers, the distance from  $C_\alpha$  to the unpaired electron which localized to the N-O bond of nitroxide is around 7 Å (38).

In the case of R1 side chain, quantum mechanical ab initio methods provided precise energetics for a variety of conformational states of R1 (39-41). However, in general, these approaches are computationally too demanding for proteins in large scales. More importantly, they fail to observe thermal fluctuations. Based on classical force fields molecular dynamics (MD) simulations offered a more realistic substitute method to investigate the conformational dynamics

of the R1 side chains (42,43). The results acquired from the MD simulations analysis agreed with the available X-ray crystallography data (44).

**Figure 1.5** Structure of residue R1 formed by reaction of the MTSSL with a cysteine residue with dihedral angles  $\chi_1$ – $\chi_5$  noted in red

In 2010, Gunnar Jeschke group (45) showed that libraries of around 200 rotamers from a repetitive projection of a long molecular dynamics trajectory of the unrestrained MTSSL onto a canonical dihedral angles ensemble as shown in Figure 1.6 (black lines). It provided a representation of the fundamental trajectory sufficient for EPR distance measurements. To characterize the set of spin label rotamers on a single protein position, analysis of rotamers was carried out on spin labeled T4 lysozyme mutants. An MD simulation study of MTSSL attached to a polyalanine  $\alpha$ -helix at its central site in an explicit solvent was performed (43). They simulated EPR spectra using the MD trajectories and comprising global dihedral angles diffusion appropriate for T4 lysozyme tumbling in solution as presented in Figure 1.6 (red bars).

Using Density Functional Theory (DFT) computations, Wayne L. Hubbell *et al.* performed conformational analysis of the R1 side chain in an  $\alpha$ -helix to calculate the energies of rotameric states in solution (39). The energy minima corresponding to the  $\chi_1$ – $\chi_3$  rotamers were shown in Figure 1.6 (green bars). Besides, the blue lines in Figure 1.6 represented the dihedral angles observed in protein crystal structures attached MTSSL. These data were collected from different references (22,46-56) by Gunnar Jeschke (37). For angles  $\chi_1$ ,  $\chi_2$ , and  $\chi_4$ , potential energy minima were found at  $-60^\circ$ ,  $60^\circ$ , and  $180^\circ$ . Meanwhile,  $\chi_3$  and  $\chi_5$  potentials have minima at  $-90^\circ$  and  $90^\circ$ . The dihedral angles distributions obtained from MD simulations of MTSSL attached into the central cysteine of a pentadeca glycine helix approximately consistent with the minima of expectation (57).

In MD simulations, transitions between different positions of  $\chi_1$  and  $\chi_2$  are slower (58) than those of  $\chi_4$  and  $\chi_5$ . Besides, the dynamics of the MTSSL probes to  $\alpha$ -helix was studied to

rationalize its impacts on EPR spectra (41). Conformational profiles of the side chain bonds were calculated by ab initio method. A limited number of allowed rotamers was determined that undergo rotational oscillations and jumps. In particular, the transitions frequency between  $\chi_5$  states are affected by the other rotamers, especially on  $\chi_4$ , and can be very high for some conformations due to an almost flat  $\chi_5$  potential.

**Figure 1.6** Distribution of dihedral angles in the spin-labeled residue R1 formed by reaction of the MTSSL with a cysteine residue (37); p, t, and m states stand for plus, trans, and minus values of angle, respectively, which are alternative for gauche(+), trans, and gauche(-) nomenclature by IUPAC.

#### 1.4 Objectives

1. To model structures of cysteine-mutated membrane protein with nitroxide spin label attaching at various positions
2. To investigate structural and dynamic properties of spin label in membrane protein
3. To categorize all spin label sites in the protein based on different local environments

## Chapter 2

### METHODOLOGY

#### 2.1 Constructing structure models of the spin labeled protein

The crystal structure of KvAP-VSD (PDB code: 1ORS) was used to construct protein structure models containing the nitroxide spin label side chain. In the study, the spin label was attached to an amino acid position one at a time throughout the KvAP-VSD structure. The structure coordinates available in PDB consist of four transmembrane segments (TMs) spanning from residues 20 to 151 (132 residues). Therefore, we constructed a total of 132 structure models attached with the spin label moiety through the CHARMM-GUI web server (59) (<http://www.charmm-gui.org>), (15) as illustrated in Figure 2.2(a, b). All the 132 structure models were subsequently subjected to build the protein-lipid systems for membrane protein simulations which were described in the next section.

#### 2.2 Molecular dynamics details

##### 2.2.1 Preparation of simulation systems

In the next step, each spin label-attached KvAP-VSD was embedded in the phospholipid bilayer of POPC (1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine). The structure of POPC molecule is shown in Figure 2.1. The protein-lipid systems were solvated with the TIP3P water molecules (60). The simulation box was roughly  $84 \times 81 \times 90 \text{ \AA}^3$  in size. The  $\text{Na}^+$  and  $\text{Cl}^-$  counterions were used to neutralize the systems with the salt concentration of 0.1 M. Figure 2.2 shows one example of preparing the system by CHARMM-GUI in Figure 2.2(a, b) and VMD software in Figure 2.2(b, c).

**Figure 2.1** Chemical structure of POPC molecule

**Figure 2.2** An example for constructing systems using CHARMM-GUI and VMD software

### 2.2.2 MD simulations

An all-atom molecular dynamics (MD) simulation was performed using NAMD program (version 2.11) (61). Periodic boundary conditions were applied. The CHARMM36 (62) force fields were used to calculate the interatomic interactions for protein and lipid. The force field parameters of the spin label were also provided from CHARMM-GUI platform. The long-range electrostatic interactions are calculated by the particle mesh Ewald (PME) method (63). The simulation time was 100 ns for testing of some random systems and then 10 ns for all, which was discussed in more detail in the part of system stability. During the simulation time, the average temperature and pressure were controlled at 298 K and 1 atm using Langevin dynamics and Nosé-Hoover Langevin piston method, respectively. The switch and cutoff were 10 and 12 Å, respectively. The SHAKE algorithm (64) was employed. The time step was 1 fs. MD trajectories were saved every 1 ps.

### 2.3 Molecular dynamics trajectory analysis

To study the conformation dynamics of spin label side chains in the membrane protein, we did calculate the root-mean-square deviation and root-mean-square fluctuation quantities. In addition, we applied the radial distribution function (RDF) method to categorize the spin label side chains in different local environments (water, lipid, and buried site).

### 2.3.1 Root-mean-square deviation calculations

Root-mean-square deviation (RMSD) was calculated as a quantitative measure of the similarity between two superpositions of atoms. Therefore, it can be used to evaluate how the system deviates from the initial crystal conformation. The RMSD value of the backbone C $\alpha$  atoms is measured in Å, using the following equation:

$$RMSD(t_1, t_0) = \left[ \frac{1}{M} \sum m_i \| r_i(t_1) - r_i(t_0) \|^2 \right]^{\frac{1}{2}} \quad (1)$$

where  $M$  is the mass of all atoms,  $m_i$  and  $r_i$  are the mass and position of atom  $i$ , respectively; and time  $t_0$  refers to the reference position (crystal structure).

### 2.3.2 Root-mean-square fluctuation calculations

To determine the structural variation, the residue-by-residue root-mean-square fluctuation (RMSF) of the backbone C $\alpha$  atoms or nitrogen atom of nitroxides (for spin label side chains) from their average locations were computed by the formula as follows:

$$RMSF_i = \left[ \frac{1}{T} \frac{1}{M} \sum m_i \langle (r_{ij}(t) - \bar{r}_{ij})^2 \rangle_{MD} \right]^{\frac{1}{2}} \quad (2)$$

where  $T$  is the equilibrated MD trajectories.

The dynamics of spin label side chains measured from RMSF were compared to the experimental data (16).

### 2.3.3 Radial distribution function

The radial distribution function  $g(r)$  was computed to reveal the average distribution of the atoms in the surrounding of spin label side chains. It can be represented by a pair correlation functions  $g_{AB}(r)$  between two atoms A and B as shown in equation (3). These quantities can be used to characterize the side chain sites based on the different immediate environments such as water, lipid, and membrane protein itself.

$$g_{AB}(r) = \frac{\langle \rho_B(r) \rangle}{\langle \rho_B \rangle_{local}} \quad (3)$$

where  $\rho_B$  is the probability density of finding atom B as a function of distance ( $r$ ) between A and B atoms.

All the method described above are summarized in Figure 2.3

**Figure 2.3** Diagram of the main steps in this study

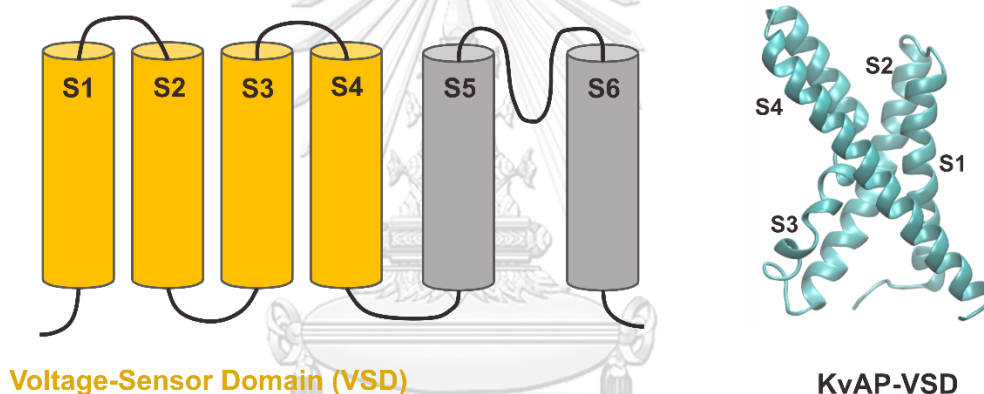

## Chapter 3

### RESULTS AND DISCUSSION

As staged, this study aims to characterize the geometrical and dynamical properties of the spin label in membrane protein systems. We have performed MD simulations of KvAP-VSD as it represents a simple model system to study the structure and mobility of nitroxide spin labels. The voltage sensor domain of KvAP consists of 132 amino acid residues (the residues numbered from 20 to 151) with four transmembrane segments (S1-S4) as described in Figure 3.1. The KvAP structure has been resolved at 1.9Å resolution. In addition, the EPR data of spin labeled KvAP-VSD are available for a detailed interpretation of the position dependent behavior of the spin label in different surrounding environments such as in the membrane-exposed regions, water-exposed regions and buried regions.

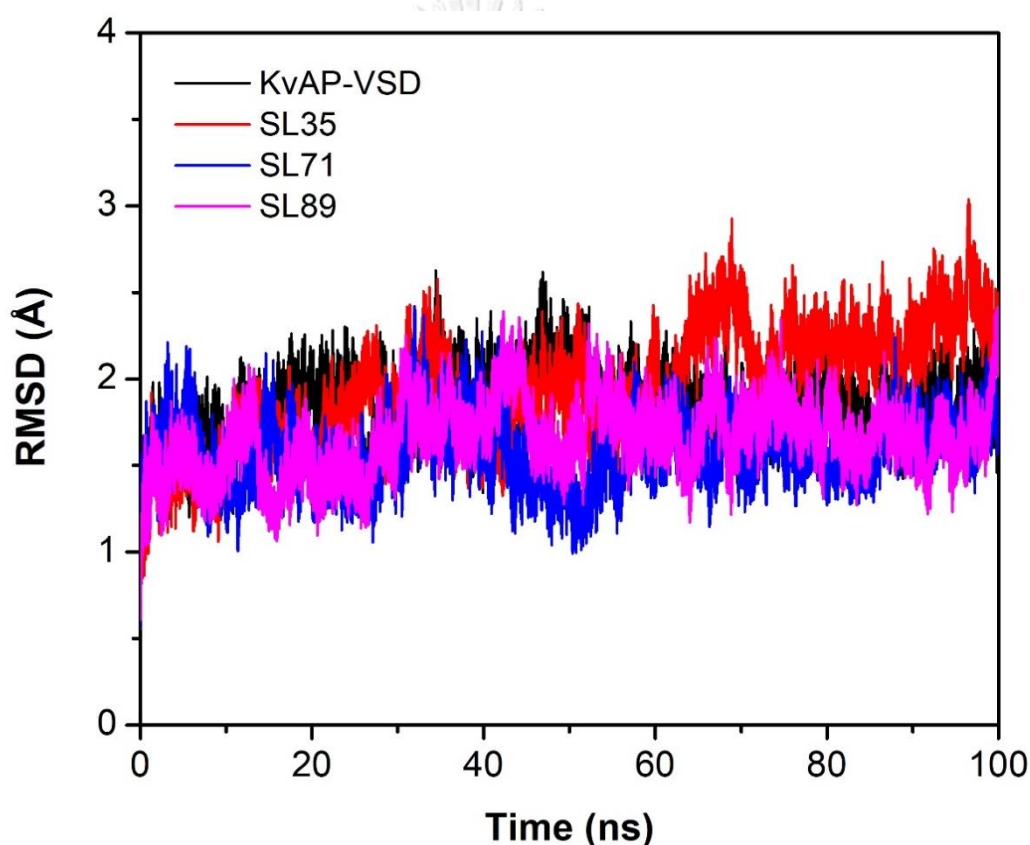

**Figure 3.1** Schematic diagram of voltage-sensor domain (VSD) with four segments (S1-S4) in typical structure of voltage-gated ion channels (S1-S6) and structure of KvAP voltage-sensor domain (KvAP-VSD)

#### 3.1 Characterization of the backbone dynamics

It should be noted that there were a large number of the spin labeled KvAP-VSD systems to be carried for MD simulations (a total of 132 independent runs). It is necessary to reduce the CPU time to compensate computational costs. We decided to perform the simulation of 10-ns in length as we were interested only local motion of the spin label side chain. Moreover, the experimental EPR data indicated that the protein structure was minimally perturbed by the presence of nitroxide side chain. However, it is important to examine a range of spin label conformations which were sufficiently captured by MD simulations with fairly small time and length scales. As a control, four systems were randomly chosen for carrying out a relatively long simulation (100-ns).

These are the unlabeled and three spin-labeled KvAP-VSD systems which are denoted as KvAP-VSD, SL35, SL71, and SL89, respectively. The numbers, 35, 71, and 89 correspond to the residue number where the spin label has been attached. Structure comparison between those from MD snapshots and the reference x-ray was analyzed using root-mean-square deviation (RMSD) calculation. The RMSD values were computed based on the backbone atoms of the protein. The MD snapshot structures were superimposed on to the reference X-ray structure (15) to discard translation and rotation of the protein molecule. The RMSD plots as a function of simulation time of the four selected systems were illustrated in Figure 3.2.

**Figure 3.2** Backbone RMSD profiles of 100 ns MD trajectories of KvAP-VSD, SL35, SL71, and SL89

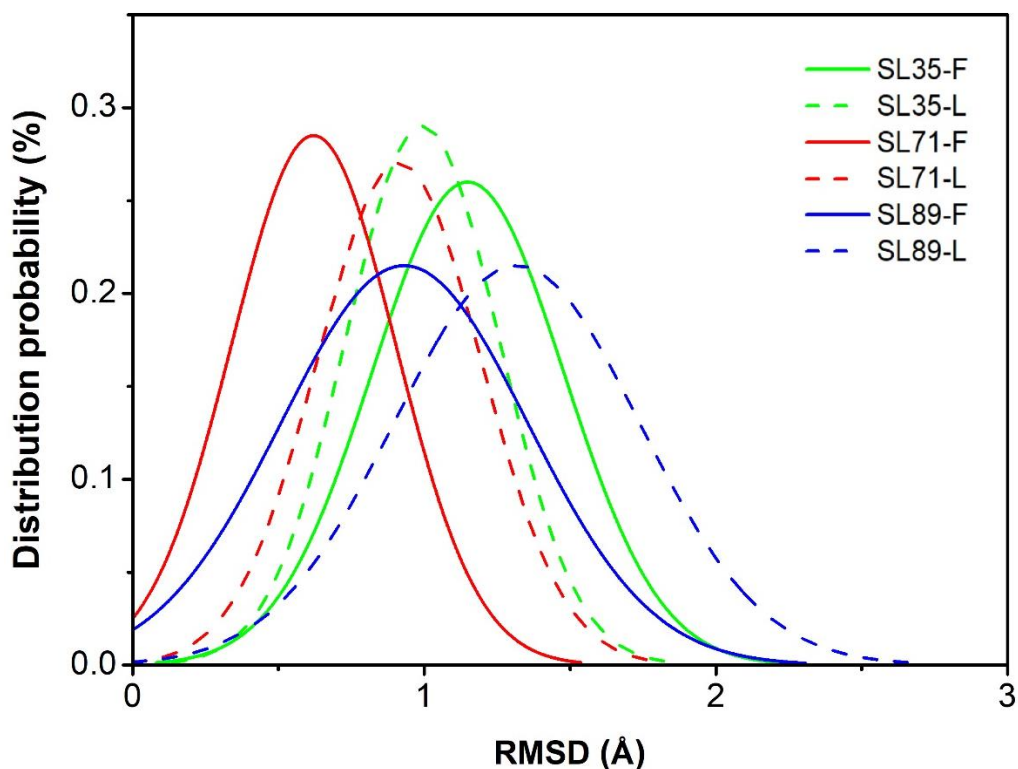

As can be seen in Figure 3.2, the backbone RMSDs in all the equilibrated production trajectories kept stable within 1.5-2.5 Å. It has also shown that in most cases it required less than 10ns for the backbone atoms to reach equilibrium. After equilibration has been reached, backbone conformations fluctuate very little with respect to their own average. To illustrate no significant

different in the global structures during the early time and near final time of the simulation, we compared the  $C_{\alpha}$  atom-RMSDs of SL35, SL71 and SL89 average over the first 10 ns and last 10 ns (the 90-100 ns interval). As summarized in Table 3.1, there were no essential difference in the movement of the backbone during the first 10 ns and last 10 ns, with the deviation of  $C_{\alpha}$ -RMSDs from 0.16-0.38 Å.

**Table 3.1** Average  $C_{\alpha}$  atom-RMSD for the first 10ns and the last 10ns of 100 ns MD simulations

System	Average RMSD (Å)		Deviation (Å)
	The first 10 ns	The last 10 ns	
SL35	1.16	1.00	0.16
SL71	0.62	0.92	0.30
SL89	0.91	1.29	0.38

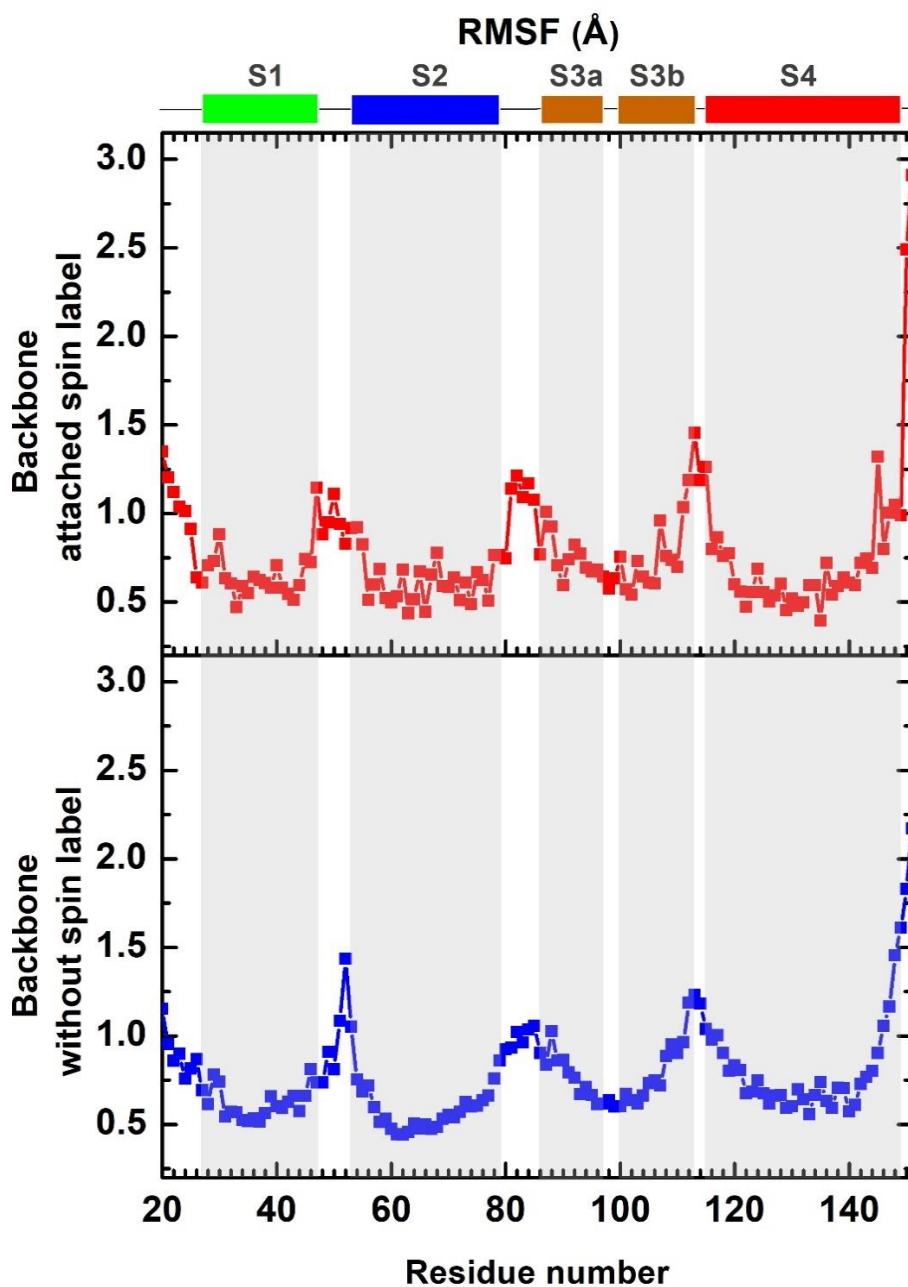

The distribution probability of  $C_{\alpha}$ -RMSD can provide structure and dynamics information of the protein. For SL35, SL71, and SL89, there were slightly shifted in the  $C_{\alpha}$ -RMSD distribution from the first 10ns to last 10ns of simulations (Figure 3.3). This suggested that the VSD structure remains unchanged relative to their average structure during the simulations. Furthermore, global dynamics at the early and final simulation times were nearly unaltered as shown by a similar distribution shape during the first and last 10ns of simulations. From the results, we can conclude that the VSD has reached a well-defined structural equilibrium after few nanoseconds of simulations. It also implied that MD simulation of ten nanosecond timescale for KvAP-VSD would be sufficient to capture the spin label dynamics with an amplitude of the nitroxide motion in a range of 1-5 Å. This finding has led us to set the simulation time length to 10ns for the remaining 129 systems since we were interested to investigate the conformational dynamics of nitroxide spin label side chains.

**Figure 3.3** Distribution probability of  $C\alpha$ -RMSD of SL35 (green), SL71 (red), and SL89 (blue) over the first 10 ns (SL35-F, SL71-F, SL89-F; solid lines) and the last 10 ns (90-100 ns interval) (SL35-L, SL71-L, SL89-L; dash lines).

### 3.2 Dynamics properties of spin label side chains

To identify the mobility of spin label relative to the protein motion, the root-mean-square fluctuation (RMSF) with respect to the average structure was analyzed using the simulation time duration of 5-10 ns. Figure 3.4 shows backbone RMSF values for 132 positions of spin labeled KvAP-VSD in comparison with those of unlabeled VSD. As can be seen, a relatively high RMSF at the N- and C- terminals, the loops (S12, S23, and S34) between transmembrane segments usually possessed the prominent peaks of RMSFs, revealing their greater structure flexibilities than the S1, S2, S3, and S4 segments. The mobility of transmembrane segments was reduced in comparison with that of the non-transmembrane regions. The movement of the backbone inside membrane is more restricted in part due to the formation of stable  $\alpha$ -helix whereas the greater motion of the backbone outside membrane is attributed by flexible random-coil. From the results, the protein is less flexible.

**Figure 3.4** RMSF of backbone without spin label (blue line) and backbone attached spin label (red line) with the similar pattern. Residues in transmembrane regions (S1, S2, S3 and S4) are highlighted in gray. The S3 helix breaks into S3a and S3b.

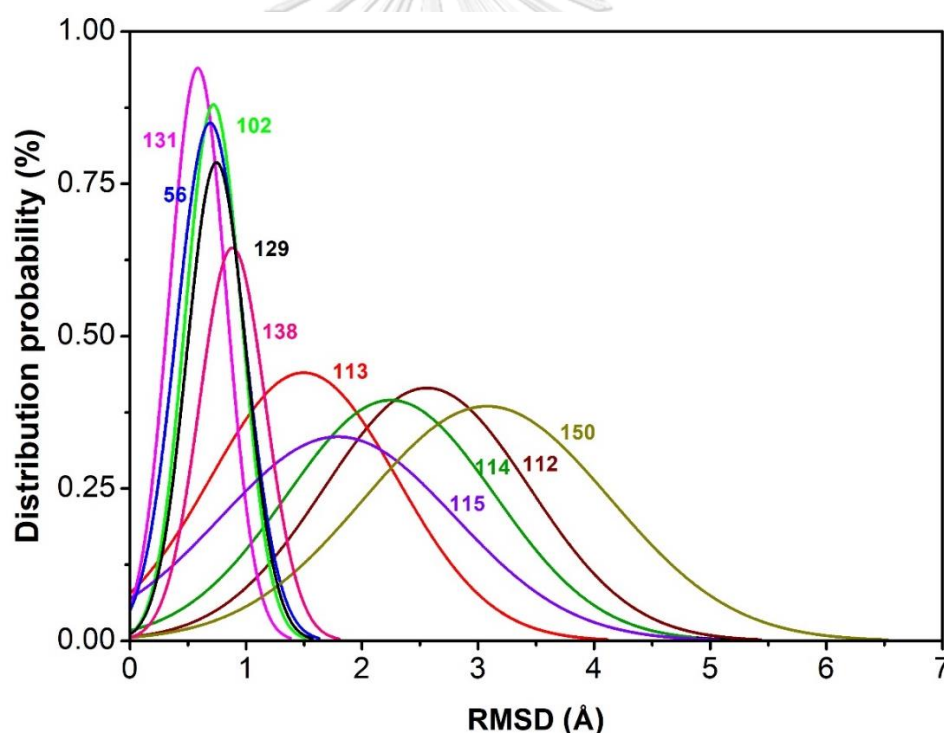

In addition, an RMSF comparison between spin labeled and unlabeled KvAP-VSD provides information about the influence of spin label on the protein structure. It was, however, found that the profile pattern of the backbone RMSF of spin labeled KvAP-VSD was not significantly different from that of unlabeled KvAP-VSD. This suggested that attaching the spin

label into the protein did not severely affect KvAP-VSD structure. The MD results were consistent with experimentally-determined EPR data. This also suggested that we can investigate the dynamics behavior of the spin label from our simulation data.

**Figure 3.5** RMSF (red line) and mobility (16) (blue line) of spin label side chains. Dynamics of spin label side chains in S3 helix were remarkably varied due to the mid-helix break of S3. Both RMSF and mobility in the plot show the helical periodicity in membrane regions.

The flexibility of each nitroxide side chain on KvAP-VSD was evaluated in terms of RMSF. Figure 3.5 showed a comparison between RMSF of nitroxide side chain and the experimental mobility ( $\Delta H^{-1}$ ). The RMSF profile of transmembrane segments has, on average, a periodic characteristic of helix, similar to the experimental mobility. Both RMSF and mobility showed a similar trend in such a way that the spin label mobility was high in the loops and more restricted in membrane regions. This suggested that the dynamics motion of spin label side chains from MD simulations was overall in good agreement with the experimental mobility (16). It appears that the spin label with high mobility showed a broader  $C_{\alpha}$ -RMSD distributions (residues 112-115, and 150) whereas that with low mobility (residues 56, 102, 129, 131, and 138) exhibited a sharp  $C_{\alpha}$ -RMSD distributions (Figure 3.6). This suggested that conformational dynamics of the nitroxide spin label was connected with the movement of the protein backbone.

**Figure 3.6** Distribution probability of  $C_{\alpha}$ -RMSD of some selected residues 56, 102, 112, 113, 114, 115, 129, 131, 138, and 150. Sharp distributions appear at residues 56, 102, 129, 131, and 138. Broader distributions appear at residues 112-115, and 150.

To visualize the variation of the spin label dynamics with respect to their position on the KvAP-VSD structure, color mapping method was applied for both RMSF (residues 20-151) and mobility (residues 20-147) profiles as illustrated in Figure 3.7. The color ranged from blue to red

to represent from low to high dynamics of the spin label side chains using VMD software. Most areas of blue color located in the intramembrane while the white and red colors commonly appeared near or in extramembrane regions.

**Figure 3.7** Color mapping of the RMSF and mobility data of spin label side chains. Color ranges from blue to red corresponding to the increasing of spin label dynamics using VMD software.

The RMSF and mobility distributions of all spin label side chains in four segments (S1-S4) and loops (S12 and S23) were also calculated and plotted using box charts in Figure 3.8 and Figure 3.9, respectively. There was only one residue connecting S3 and S4, hence S34 loop can be neglected. The average RMSF and mobility from EPR data of R1 side chains in each segment and loops were also computed and shown in Table 3.2.

**Table 3.2** Average RMSFs and mobility of spin label side chains in each segment and loop

Average value	S1	S12	S2	S23	S3	S4
RMSF (Å)	0.88	0.96	0.83	1.07	0.98	0.77
Mobility ( $g^{-1}$ )	0.20	0.26	0.23	0.30	0.22	0.22

The loop S23 shows the largest average of both RMSF (1.07 Å) and mobility (0.30  $g^{-1}$ ). The average RMSF of S12 had approximate value with S3, 0.96 ~ 0.98 Å. However, in term of mobility, S12 had higher mobility than S3, 0.26 > 0.22  $g^{-1}$ . For S1, S2, and S4, their average RMSF

and mobility values were all smaller than those of S12 and S23 as seen in Figure 3.8 and 3.9. From the results, spin label side chains in the loops were more mobile than those in the segments.

**Figure 3.8** RMSF distributions of spin labels in the segments (S1-S4) and the loops (S12 and S23) sites

**Figure 3.9** Mobility distributions of spin labels in the segments (S1-S4) and the loops (S12 and S23) sites

### 3.3 Structural fluctuations of spin label side chains

To understand the conformational dynamics of the nitroxide spin label in the membrane system environment, dihedral angles associated with all rotational bonds within the spin label side chain were defined as follows:  $\chi_1$ : CA-CB,  $\chi_2$ : CB-SG,  $\chi_3$ : SG-S1L,  $\chi_4$ : S1L-C1L, and  $\chi_5$ : C1L-C1R (Figure 3.10). The rotational motion of the nitroxide spin label linked to these dihedral angles were calculated during the last 1 ns MD trajectories. The dihedral angles averaged over 132 MD systems showed a general tendency of the preferred orientation of the spin label in KvAP-VSD.

The dihedral angles ranged from  $-180^\circ$  to  $+180^\circ$  whereas the confidence interval was  $\pm 30^\circ$ , using the right-handed rotation rule in which if it represents a clockwise direction with the axis oriented towards the end of the side chain, this angle is positive and vice versa. The central bond of NA-CA-CB-SG ( $\chi_1$ ) rotations were distributed at  $\pm 60^\circ$  and  $\pm 180^\circ$ . For CA-CB-SG-S1L fragment,  $\chi_2$  angle values were located at  $\pm 75^\circ$ ,  $\pm 180^\circ$ , and slightly changed to  $\pm 60^\circ$ ,  $\pm 150^\circ$ , respectively. The CB-SG-S1L-C1L dihedral angles ( $\chi_3$ ) were found at only two regions of  $90^\circ$  and  $-90^\circ$  owing to the intrinsic barrier of the disulfide bond (65). The  $\chi_4$  dihedral angles in SG-S1L-C1L-C1R configurations were relatively unhindered and the most fluctuated ones (19). In particular,  $\chi_4$  ranged from  $\pm 60^\circ$  to  $\pm 180^\circ$ . In the case of  $\chi_5$  rotational conformations, they spread from  $0$  to  $\pm 120^\circ$  which were restrained by the interaction potential of the S1L atom with the  $\alpha$ -CH<sub>3</sub> groups and the 4-H of the nitroxide ring (19).

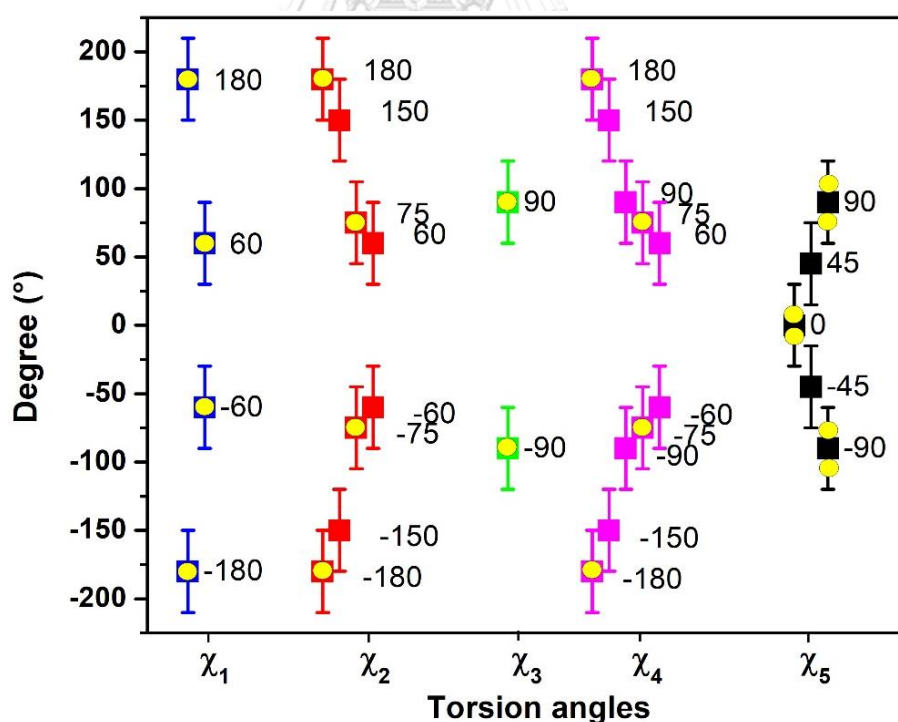

**Figure 3.10** Definition of dihedral angles ( $\chi_1$ -  $\chi_5$ ) of MTSSL and nitroxide-C $\alpha$  distance (r)

As summarized in Table 3.3 and Figure 3.11, the nitroxide side chain adopts particular conformations implying preferred rotamers of the spin label. All detailed plots of these rotamers were presented in Supplementary figures (Appendices) Figure S1-S15. The values of the  $\chi_1$ - $\chi_5$  obtained in this study were in good agreement with those obtained by *ab initio* calculations (41) for the spin label attaching in Poly-Ala  $\alpha$ -helix (Figure 3.11).

**Table 3.3** Average values of the dihedral angles

Type	MD simulations ( $\pm 30$ deg)	<i>Ab initio</i> computation (41)
$\chi_1$ (deg)	$\pm 60, \pm 180$	$-60, +65, \pm 180$
$\chi_2$ (deg)	$\pm 60, \pm 75, \pm 150, \pm 180$	$\pm 75, \pm 180$
$\chi_3$ (deg)	$\pm 90$	$\pm 90$
$\chi_4$ (deg)	$\pm 60, \pm 75, \pm 90, \pm 150, \pm 180$	$\pm 75, \pm 180$
$\chi_5$ (deg)	$0, \pm 45, \pm 90$	$\pm 8, \pm 77, \pm 100$

**Figure 3.11** Dihedral angle distribution for  $\chi_1$ ,  $\chi_2$ ,  $\chi_3$ ,  $\chi_4$ , and  $\chi_5$  represented by blue, red, green, purple, and black color symbols, respectively. Its average coincides with the value obtained from *ab initio* calculations (yellow circles).

Depending on those rotational conformers, nitroxide-C $\alpha$  distances were also varied. The average distances of nitroxide-C $\alpha$  of all spin label side chains in the KvAP-VSD structure were also examined and reported in Figure 3.12. The distance variation was from  $\sim 6.5$ -10 Å and the global average distance is about 8.5 Å as shown by the gray dash line in Figure 3.12. According to De Sensi, S. C., *et. al.*, the distance from C $\alpha$  to the unpaired electron which localized to the N-O bond of nitroxide was  $\sim 7$  Å when MTSSL attached in T4 lysozyme (38).

**Figure 3.12** Nitroxide-C $\alpha$  distance variation of all spin labels over the last 1 ns simulation time with average value of 8.5 Å.

### 3.4 Categories of spin label side chains

To obtain information about surrounding environments of the spin label, the Radial Distribution Function (RDF) plots were generated using the last 2 ns simulations. The environmental RDF analysis over 132 different spin label sites allowed to cluster the spin label side

chain in KvAP-VSD into three categories. These are water-exposed, lipid-exposed and amino acids (protein-buried) spin labels.

**Figure 3.13** Radial distribution function  $g(r)$  over the last 2-ns simulations of typical spin label side chains: SL35 (black lines), SL62 (red lines), and SL103 (green lines) in the three different local environments (A) nitroxide-protein, (B) nitroxide-lipid, and (C) nitroxide-water. Atom selections of nitroxide were ON and NN atoms. For water and lipid, atom selections were chains

W and L, respectively. For protein (buried), the protein residues (except two adjacent residues) were selected.

Figure 3.13 shows typical patterns of RDFs for the three neighboring categories of the spin label in KvAP-VSD (SL35, SL62, and SL103). The spin label of SL35 (black lines) was exposed to water as shown by the first peak of the spin label-water RDF at a distance of about 2 Å while that of SL103 (green lines) was exposed to lipid at around 6 Å distance. The spin label of SL62 was found to be buried inside the protein by orienting towards the central core of VSD (Figure 3.14). However, it also contacts with water molecules as indicated by a peak of the RDF of spin label-water at ~2 Å. This suggested that water molecules were accessible into the VSD core during the simulations. The results were consistent with experimental and simulation data reported previously.

**Figure 3.14** Spin label side chains in their different immediate environments: SL35 (water-exposed), SL62 (buried), and SL103 (lipid-exposed)

The Poisson-Boltzmann electrostatic potential molecular surface of KvAP-VSD was determined using APBS (Adaptive Poisson-Boltzmann Solver) program and demonstrated in Figure 3.15. Red represented areas of the most negative electrostatic potential. The most positive electrostatic potential regions were represented by blue. White represented zero potential regions. Potential increases in the order red < white < blue. More polar the molecule was, larger red/blue differences appeared. For nonpolar areas, the surface had brighter shades. In Figure 3.15, therefore, it is obvious that water molecules are able to penetrate into the VSD hole and then interact with the spin label side chains.

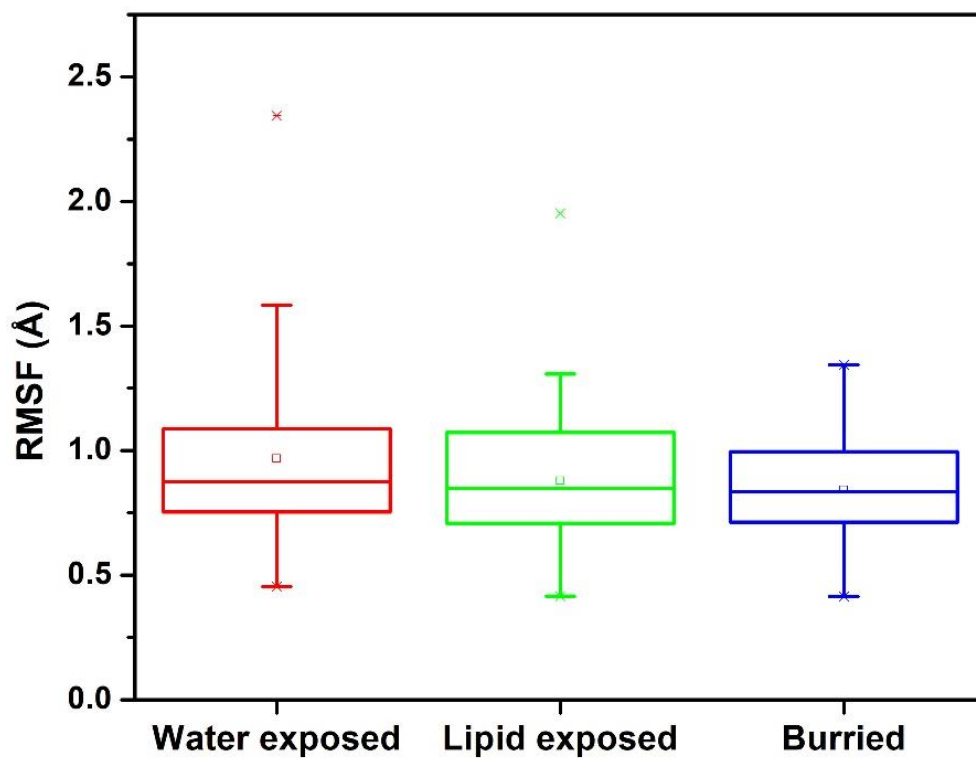

**Figure 3.15** Molecular surface of KvAP-VSD mapped using Poisson-Boltzmann electrostatic potential

**Table 3.4** Average RMSF and mobility of each category of spin label side chains

Type	Water exposed	Lipid exposed	Buried
RMSF (Å)	0.97	0.88	0.84
Mobility ( $g^{-1}$ )	0.24	0.22	0.21

The average RMSF and mobility of each spin label side-chain group were calculated and shown in Table 3.4. Additionally, we constructed the distribution RMSF and mobility data for each spin label category using box plots as in Figure 3.16 and 3.17. In both graphs, the water-exposed spin label side chains were more flexible than the lipid-exposed ones while the buried spin labels had the slowest motions. The correlation between the normalized values of the average RMSF and mobility for each group of spin label side chains was identified and expressed in Figure 3.18. The square of the correlation value ( $R^2$ ) was equal to 0.9994, implying that the dynamical properties of characterized spin label sites in the protein highly consistent with the experimental EPR data. The

drawback of this approach is that some spin label side chains can expose to two environments at the same time (interface regions).

**Figure 3.16** RMSF box plot of each category of spin label side chains: water-exposed (red box), lipid-exposed (green box), and buried (blue box)

Figure 3.17 Mobility box plot of each category of spin label side chains: water-exposed (red box), lipid-exposed (green box), and buried (blue box)

## Chapter 4

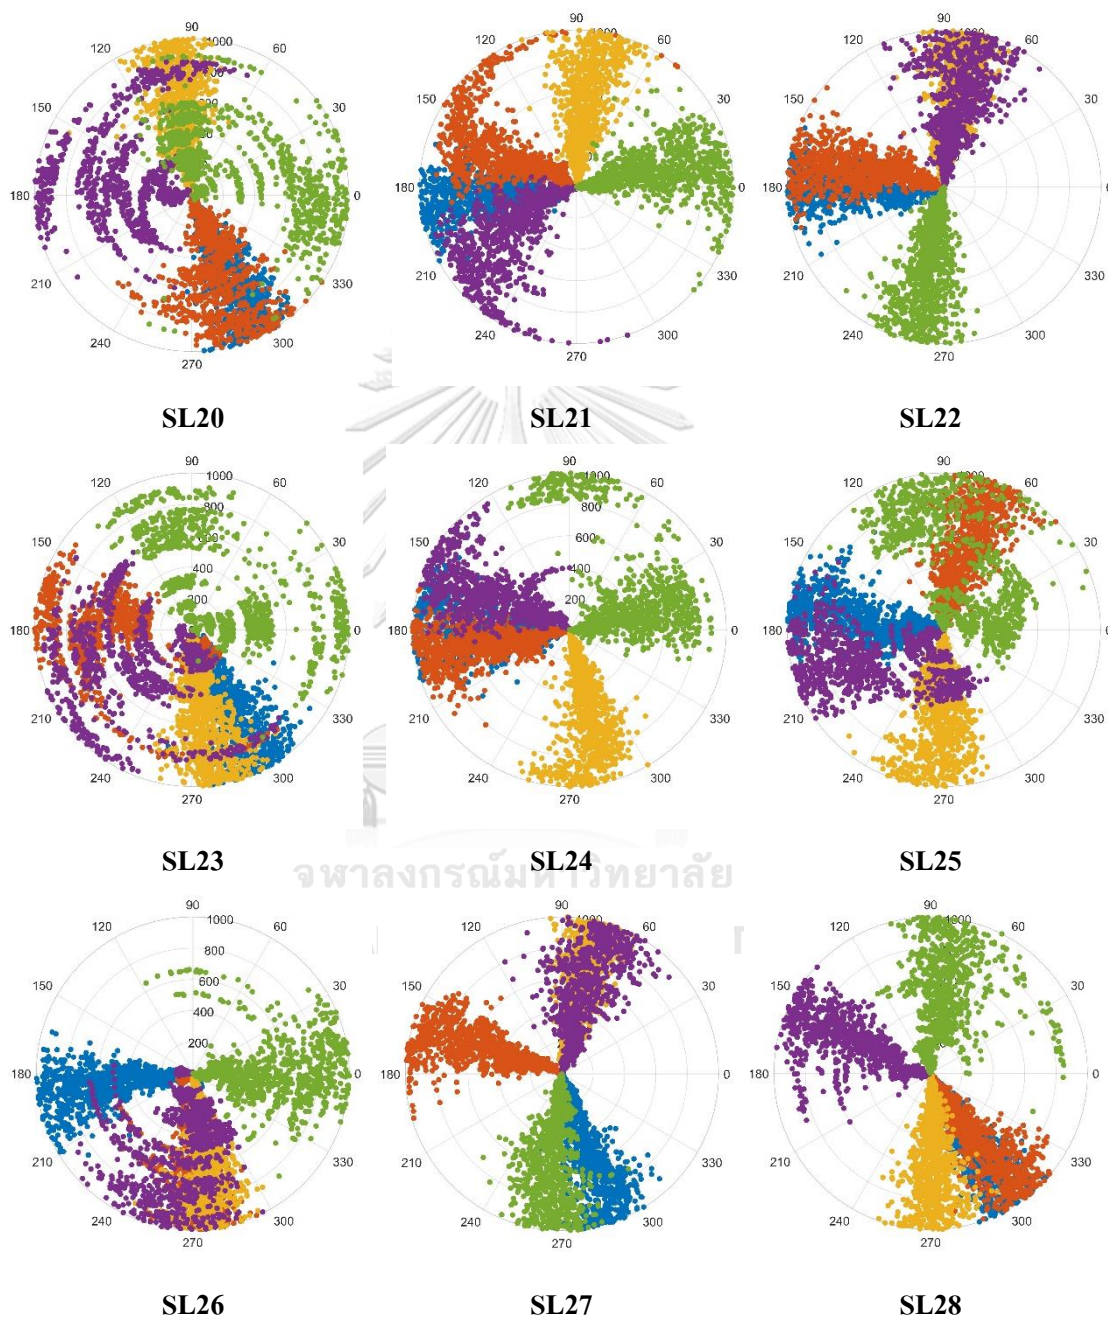

### CONCLUSIONS

We constructed structures of the cysteine-mutated membrane protein with the nitroxide spin label attaching at 132 positions (residues 20-151) of the KvAP voltage sensor domain (VSD), using CHARMM-GUI and VMD. Next, all-atom MD simulations were performed over 10 ns for all systems, then analyzing MD trajectories. Root-mean-square fluctuation (RMSF) of each spin label side-chain was calculated and compared with the experimental mobility data. The spin label side chains attached in the loops were more flexible than those in the segments, which was well consistent with the experimental EPR data.

Importantly, it was found that owing to the similar pattern in RMSF plots, the mobility of the spin label side-chain can be used to reflect the backbone dynamics. The conformational fluctuations of spin label side chains were represented by the dihedral angle distribution and the variation of the nitroxide-C $\alpha$  distances. Moreover, the categories of the spin label side chains based on the local environments were also established using radial distribution function (RDF) method. Besides, the dynamics of the spin label side chains were decreased in the order water-exposed > lipid-exposed > buried type.

## SUPPORTING INFORMATION

## VITA

**NAME** Ngoc Lan Le Nguyen

**DATE OF BIRTH** 20 October 1995

**PLACE OF BIRTH** Phu Cat district, Binh Dinh province, Vietnam

**INSTITUTIONS ATTENDED** Department of Chemistry, Faculty of Science, Chulalongkorn University

**HOME ADDRESS** 488/18 Phetchaburi Road, Thung Phaya Thai, Khet Ratchathewi, Bangkok 10400
