## 4876598433: MAJOR PHARMACOLOGY

KEYWORD: PLAII OIL / AORTA / CALCIUM / VASCULAR SMOOTH MUSCLE

RUNGNAPA MESRIPONG: EFFECTS OF OIL FROM ZINGIBER CASSUMUNAR

ROXB.ON VASCULAR TONE OF ISOLATED RAT AORTA: ASST. PROF. SUREE

JIANMONGKOL, Ph.D., 90 pp.

Plai (*Zingiber cassumunar* Roxb.) is one of Thai herbal plants, which is well recognized for relieving muscle pain. In this study, the effects of plai oil on the contraction and relaxation of vascular smooth muscle in the endothelium-intact and endothelium-denuded rat aorta were investigated. The thoracic aorta was isolated from male Wistar rats (250-300 g), and the vascular tensions were measured isometrically. The results showed that plai oil (50 - 200  $\mu\text{g/ml}$ ) significantly inhibited the PE- and KCl-induced contraction of endothelium-denuded aorta in concentration-dependent manner, but had no effects in endothelium-intact aorta. In addition, plai oil (40 and 100  $\mu\text{g/ml}$ ) significantly inhibited the PE-induced contraction in  $\text{Ca}^{2+}$ -free condition, but not the caffeine-induced contraction. Furthermore, plai oil (50 and 100  $\mu\text{g/ml}$ ) suppressed  $\text{CaCl}_2$ -induced contraction in high  $\text{K}^+$ -depolarizing solution with the apparent pD2 values of  $3.76 \pm 0.09$  and  $3.57 \pm 1.35$ , respectively. The results also demonstrated that plai oil caused vasodilatation in endothelium-intact aorta with the apparent EC 50 values of  $32.80 \pm 4.43$   $\mu\text{g/m}$ . Various compounds including methylene blue (10  $\mu\text{M}$ ), L-NAME (10  $\mu\text{M}$ ), glibenclamide (10  $\mu\text{M}$ ), indomethacin (10  $\mu\text{M}$ ), atropine (1  $\mu\text{M}$ ), propranolol (10  $\mu\text{M}$ ), and tetraethylammonium chloride (10  $\mu\text{M}$ ) significantly inhibited the relaxant effect of plai oil. In conclusion, plai oil modulated the vascular tone via endothelium-dependent and endothelium-independent pathways. The direct actions on smooth muscle were possibly linked to non-specific inhibition of  $\text{Ca}^{2+}$  influx as well as inhibition of PE-mediated  $\text{Ca}^{2+}$  release from sarcoplasmic reticulum. Moreover, plai oil may influences the vascular contractility through endothelium factors including NO-cGMP pathway, hyperpolarizing, cyclooxygenase, muscarinic receptors and  $\beta$ -adrenoceptor.

## ACKNOWLEDGEMENTS

I would like to express my sincere gratitude and appreciation to my advisor, Assistant Professor Suree Jianmongkol, Ph.D and my co-advisor, Associate Professor Prasan Dhumma-upakorn, Ph.D for their valuable advice and guidance, kindness, and encouragement during the course of experimental work, making and presentation of this thesis.

I also would like to thank the committee member: Assistant Professor Surachai Unchern, Ph.D, Assistant Professor Withaya Janthasoot and Assistant Professor Thongchai Sooksawate, Ph.D for their worth comments and suggestions.

I thank to all staff members and all officers of Department of Pharmacology, Faculty of Pharmaceutical Sciences, for providing laboratory facilities.

A partial support from the Graduate School, Chulalongkorn University from Biochemical Analysis Research Unit was gratefully acknowledged. In addition, research assistant fellowship was also awarded from RAR.

I would like to thank Thailand Institute of Scientific and Technological Research (TISTR) for research funding and supply the testing agents in this study.

## INTRODUCTION

Herbal medicine has long been proven useful for human health. Plai (*Zingiber cassumunar* Roxb.) is one of herbal plants, which is well recognized for relieving muscle pain. Plai extract and plai oil have been used as an ingredient in topical creams, ointment and massage oils for muscle analgesic action and improved topical blood circulation.

In Thailand and many Asian countries, plai is widely used in folklore remedies as a single plant or as a component of herbal medicine. For example, Prasaplai, which is Thai traditional medicine, has been used for alleviation of colicky pain and abnormal menstrual period (วิชัย รุ่งตระกูล, 2546). Various compounds in plai oil have been identified including sabinene,  $\gamma$ -terpinene,  $\alpha$ -terpinene, terpinen-4-ol, and (E)-1-(3, 4-dimethoxyphenyl) butadiene (DMPBD) (Cosey, 1971).

The pharmacological studies have been demonstrated that the rhizomes of *Z. cassumunar* have antioxidant (Lertsatitthanakorn, *et al.*, 2006) and antimicrobial activities (นันทวัน บุญยะประภัสร์, 2523). The hexane extract elicit anti-inflammatory activity (Jeenapongsa, *et al.*, 2003). (E)-1-(3, 4-dimethoxyphenyl) butadiene (DMPBD), which was isolated from the hexane extract, exhibited a strong inhibitory action on the edema formation in carrageenan-induced rat paw edema (Panthong, *et al.*, 1990; Jeenapongsa, *et al.*, 2003). In addition, phenylbutenoids, which are typical non-polar substances in the rhizomes of plai, have insecticidal activity (Nugroho, *et al.*, 1996).

Plai oil is one of essential ingredients in herbal compress (มานิช วามานนท์ และคณะ, 2537), massage oil and skin care products for anti-inflammatory effect and muscle relaxation (Wanauppathamkul, 2003). It has been demonstrated that plai extracts and its constituents inhibited agonist-induced contraction of smooth muscle in several *in vitro* models of isolated organs including guinea pig and rat trachea, guinea -pig ileum and rat uterus (เรณู โภยสุโข และคณะ, 2533). In addition, plai oil caused relaxation of smooth muscles (วัลภา อนันตศานต์, 2525; สุวรรณมา เวชอภิกุล, 2547). It has been reported that

plai-induced relaxation in isolated rat uterus and intestine was antagonized by acetylcholine, calcium chloride, but not by either alpha-blocker, beta-blocker or histamine (วัลภา อนันตศานต์, 2525).

As known, intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) is a key element in controlling vascular smooth muscle contraction (Aaronson *et al.*, 2004; Horowitz, 1996). An increase of sufficient magnitude of  $[\text{Ca}^{2+}]_i$  fully induces contraction of vascular smooth muscle (VSM). Under physiological conditions, an increasing in  $[\text{Ca}^{2+}]_i$  is attributed to a change in membrane potential (electromechanical coupling) or to an activation of specific receptor (pharmaco-mechanical coupling), resulting in an increase in  $\text{Ca}^{2+}$  influx (Orallo, 1996; Katz, 1997). On the other hand, muscle relaxation results from a decrease in  $[\text{Ca}^{2+}]_i$  which may be due to a blockade of voltage-operated calcium ion channels (VOC) or activation of  $\text{Ca}^{2+}$  efflux system such as  $\text{Ca}^{2+}$ -ATPase and  $\text{Na}^+/\text{Ca}^{2+}$  exchanger (Felder, *et al.*, 1994; Martin, *et al.*, 1999). In addition, endothelium plays a crucial role on vasorelaxation by releasing several factors such as nitric oxide (NO) and other endothelium-derived relaxing factors (EDRF) (Klabuade, 2005; Busses, *et al.*, 2002). Although there is evidence of plai-induced relaxation on several models of smooth muscle, the mechanisms of plai actions have not been extensively investigated.

This study aimed to investigate the action of oil from *Zingiber cassumunar* Roxb. on modulation of vascular tone. It is possible that oil from *Z. cassumunar* Roxb. may exert its vasorelaxant action via endothelium-dependent and -independent pathways. Hence, this study is designed to examine the direct effect of oil from *Z. cassumunar* Roxb. on smooth muscle contractility including the interference of  $\text{Ca}^{2+}$  influx as well as  $\text{Ca}^{2+}$  release from sarcoplasmic reticulum (SR). In addition, the influence of oil from *Z. cassumunar* Roxb. on endothelium function is also investigated, including the NO-cGMP pathway, the hyperpolarization factors and activation of  $\beta_2$ -adrenergic system.

## Hypothesis

Oil from *Zingiber cassumunar* Roxb. modulates vascular tone via endothelium-dependent and –independent pathways. It is possible that oil from *Z. cassumunar* Roxb. directly affects smooth muscle by disrupting calcium influx through voltage-operated calcium ion channels, and  $\text{Ca}^{2+}$  mobilization within smooth muscle cells. Moreover, oil from *Z. cassumunar* Roxb. may activate endothelium to release certain relaxing factors such as NO.

## Objectives

1. To investigate the effects of oil from *Z. cassumunar* Roxb. on the contraction and relaxation of vascular smooth muscle in the endothelium intact and endothelium-denuded rat aorta.
2. To examine the mechanisms of action of oil from *Z. cassumunar* Roxb. in modulating vascular tone.

## Expected Benefit and Application

This study will provide new pharmacological knowledge on the effects of oil from *Z. cassumunar* Roxb. on the contraction of vascular smooth muscle as well as its mechanisms of action. The information from this study will be useful for the further application in herbal and traditional medicine development as well as for prediction the potential adverse effects on the vascular system.

## CHAPTER II

### LITERATURE REVIEWS

Plai (*Zingiber cassumumar* Roxb.) is a Thai herbal plant which has been used for medicinal purposes in Thailand and Southeast Asia for centuries (สมสุข มัจฉาชีพ, 2534). The rhizome has a yellow to green color with fleshy thick texture containing multiple sessile tubers. The characteristic of plai include as follow: distichous leaves, oblong-lanceolate, very short ligule, bilobed, pubescent. Spike ovoidellipsoid are bracts greenish red, narrowly obovate or rhomboid and calyx truncate, glabrous. Corolla tube has pale yellow, dorsal lobe cymbiform, lateral lobe linearlanceolate. Labellum is pale yellow, suborbicular, apex emarginate, lateral lobe ovate-oblong, appendage slightly longer than anther (มานิช วามานนท์ และคณะ, 2537) (Figure. 1). The odor is reported as strong and reminiscent of a mixture of ginger, camphor and turmeric. The taste is hot and camphoraceous, pleasant aromatic and taste are pungent. Essential oil of plai can be steam distilled from the rhizome and has a pale amber color. The scent is a cool, green peppery one with a touch of a bite.

Figure 1 *Zingiber cassumumar* Roxb. aerial and underground parts  
(From; <http://www.tistr.or.th/pharma/Zingiber%20cassumunar.htm> and  
[http://www.rspg.thaigov.net/plants\\_data/use/herbs14.htm](http://www.rspg.thaigov.net/plants_data/use/herbs14.htm) )

Rhizome of plai has essential oil of 8 % (มาโนช วาฆานนท์ และคณะ, 2537). A major part of the oil consists of monoterpenes with sabinene and terpinen-4-ol as main constituents. The main active constituents of the oil are sabinene,  $\gamma$ -terpinene,  $\alpha$ -terpinene, and the other active chemicals are curcuminoids derivatives (curcumin, cassumunarin A, B and C),  $\beta$ -sitosterol and cyclohexane derivatives, naphthoquinone derivatives, butanoid derivatives such as (E)-1-(3',4'-dimethoxyphenyl) butadiene; DMPBD (สุวรรณภา เวชฉีกุล, 2547 ; Masuda and Jitoe,1995). The major constituents in essential oil of rhizome of *Z. cassumunar* are shown in table 1.

Table1. Essential oil composition (%) of the different source rhizomes of *Zingiber cassumunar* Roxb.

(A): Indonesia, (B): Thailand-Prachinburi, (C): Thailand – TISTR

Compound	A	B	C
Sabinene	10.1	44	34.7
Terpinen-4-ol	10.2	24	32.3
$\gamma$ -Terpinene	3.6	9	6.7
$\alpha$ -Terpinene	2.0	6	3.7
DMPBD	9.8	6	7.2

(From; Wanauppathamkul , 2003.)

Major compositions of plai oil are terpinen-4-ol, sabinene, terpinene and DMPBD. Sabinene is a natural bicyclic monoterpene with the molecular formula  $C_{10}H_{16}$ . It is isolated from the cyclopentane ring fused to a cyclopropane ring. Sabinene is one of the chemical compounds that contributes to the spiciness of black pepper and is a major constituent of carrot seed oil (Wikipedia, 2006). It also occurs in tea tree oil at a low concentration. Terpinen-4-ol is terpene. It is considered the primary active ingredient of tea tree oil (Nascimento, 2005). The terpinenes are three isomeric hydrocarbons that are classified as terpenes. They each have the same molecular formula and carbon framework, but they differ in the position of carbon-carbon double bonds.  $\alpha$ -terpinene

has been isolated from cardamom and marjoram oils, and from other natural sources.  $\beta$ -terpinene has no known natural source, but can be synthesized from sabinene.  $\gamma$ -terpinene is natural compound which can be isolated from a variety of plant sources (Wikipedia, 2006).

Figure 2 Chemical structures of terpinen-4-ol and sabinene

Plai has long been regarded by Thai massage therapists as one of those oils necessary to have in their kit to combat joint and muscle problems (Wanauppathamkul, 2003). On joints inflammation from injury, plai is best combined with other oils such as black pepper (*Piper nigrum* L.) and lemon (*Citrus limon* Burm.) or neroli (*Citrus aurantium* L.), Himalayan cedarwood (*Cedrus deodora* G.) and orange (*Citrus aurantifolia* Swingle) (Chamratpan and Homchuen, 2005). These combinations decreased the swollen, eased the pain and considerably speeded up the healing intima for digestive upset had been used to counter irritable bowel syndrome (พฤตมา-จารย์ วิพุก โยคะ รัตนรังษี, 2534). The essential oils from plai have also been shown to cure acne, bruises, burnt skin, inflammation, muscle pain, insect bite and asthmatic symptoms. Plai oil has been even proven to cope with cough and respiratory symptoms as well. A number of pure compounds isolated from the plants have been shown to possess anti-microbial, topical and oral anti-inflammatory, analgesic and anti-oxidative activities

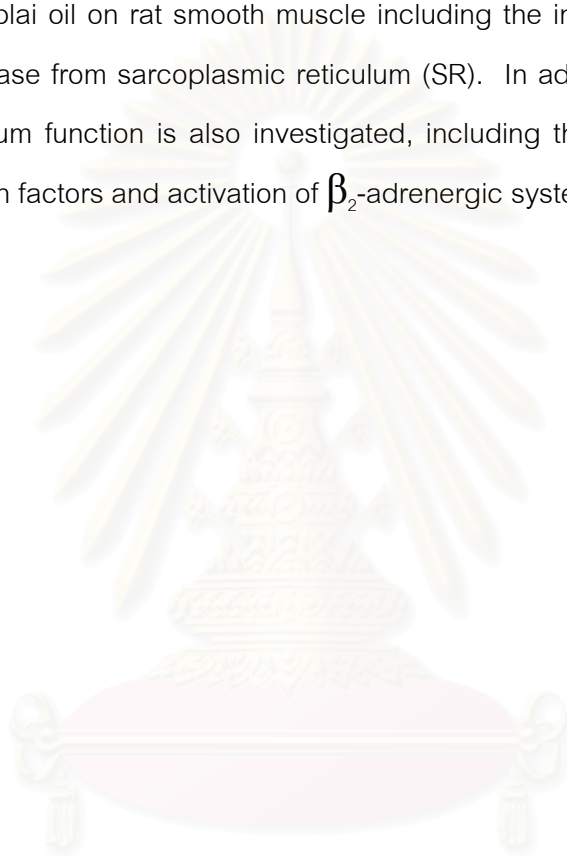

(สุวรรณมา เวชอภิภูล, 2547 ; Osaki, 1991). The fresh rhizome of plai is used in traditional Thai massage for muscle relaxant and joint pains (Wanauppathamkul, 2003).

(E)-1-(3, 4-dimethoxyphenyl) butadiene (DMPBD) which was extracted and isolated from plai exhibited antiinflammatory activity both *in vivo* and *in vitro* models. DMPBD inhibited the rat ear edema induced by ethyl phenylpropiate, arachidonic acid and 12-o-tetradecanoylphorbol 13-acetate. DMPBD possesses a potent anti-inflammatory activity through the inhibition of both cyclooxygenase (COX) and lipoxygenase (LO) pathways (Jeenapongsa, *et al.*, 2003).

Pharmacological studies of plai on smooth muscle relaxation have been reported. For example, Prasaplai has been used for colicky pain, abnormal menstrual period (วิชัย ธีวตระภูล, 2456). The rhizome of plai has been used as antiasthmatic drug in Thai traditional medicine for a long time (สุวรรณมา เวชอภิภูล, 2547). Moreover, plai was shown to reduce the size of wheal developing from intracutaneous injection of histamine in healthy volunteer. However, this antihistamic activity of plai was less potent than that of chlorpheniramine ( $P < 0.05$ ) (Piromrat, and Tuchinda., 1986).

Pure compounds from plai such as (E)-4-(3', 4'-dimethoxyphenyl) but-3-en-1-ol and (E)-4-(3', 4'-dimethoxyphenyl) but-3-en-1-ol acetate exhibited antagonistic effects on contraction of isolated guinea-pig and rat trachea in the presence of histamine and methacholine. The bronchodilator effect of plai was not attributed to stimulation of beta-adrenergic receptor (เรณู โภยสุโข และคณะ, 2533). Furthermore, (E)-4-(3', 4'-dimethoxyphenyl) but-3-en-1-ol acetate and (E)-4-(3', 4'-dimethoxyphenyl)but-3-en-1-ol acetate exhibited antagonistic effects on acetylcholine (0.06  $\mu\text{g/ml}$ ), histamine (0.3  $\mu\text{g/ml}$ ), serotonin (5  $\mu\text{g/ml}$ ) and barium chloride (0.2  $\mu\text{g/ml}$ )-induced contraction of isolated guinea-pig ileum. In addition, (E)-4-(3', 4'-dimethoxyphenyl) but-3-en-1-ol exhibited relaxant effect in uterine muscle (เรณู โภยสุโข และคณะ, 2533). In other studies, plai water extract caused smooth muscle relaxation in several isolated organ preparations including rat uterus, rat intestine and human umbilical artery (วัลภา อินันต-ศานต์, 2525). In addition, the plai induced-muscle relaxation was antagonized by acetylcholine, calcium chloride, but not by alpha-blocker, beta- blocker or histamine.

Although there are some evidences of plai-induced relaxation in several models of smooth muscle, the mechanisms of plai actions have not been extensively investigated. This study aimed to investigate the modulations action of plai oil on rat vascular tone. It is possible that plai oil may exert its vasorelaxant action via endothelium-dependent and -independent pathways. Hence, the study is designed to examine the direct effect of plai oil on rat smooth muscle including the interference of  $\text{Ca}^{2+}$  influx as well as  $\text{Ca}^{2+}$  release from sarcoplasmic reticulum (SR). In addition, the influence of plai oil on endothelium function is also investigated, including the NO-cGMP pathway, the hyperpolarization factors and activation of  $\beta_2$ -adrenergic system.

## CHAPTER III

### MATERIALS AND METHODS

#### Chemicals

Major chemicals used in this study include phenylephrine (PE), potassium chloride (KCl), acetylcholine (ACh), caffeine, tetraethylammonium (TEA), indomethacin, glibenclamide, N<sup>G</sup>-nitro -L-arginine methyl ester (L-NAME), methylene blue, atropine, propranolol, dimethyl sulfoxide (DMSO) 99.5%, terpinen – 4 - ol 98%. All chemicals were purchased from Sigma-Aldrich (St.Louis, MO) and standard sabinene from Thailand Institute of Scientific and Technological Research (TISTR).

#### Test compounds

Plai oil was obtained from Thailand Institute of Scientific and Technological Research (TISTR). The major constituents included  $\alpha$ -pinen 1.68%, sabinene 39.13%,  $\alpha$  -terpinene 2.44%,  $\gamma$ -terpinen 5.67%, terpinen-4-ol 34.12% and (E)-1-(3,4-dimethoxyphenyl)butadiene (DMPBD) 2.40%. Plai oil was dissolved in 99.5% DMSO and the final concentration of DMSO in is less than 0.07% (v/v). This concentration of DMSO had no effect on rat vascular smooth muscle contractility.

#### Preparation of aortic rings

Sixty adult male Wistar rats of body weight between 250-300 g were used in this study. They were obtained from National Laboratory Animal Center, Salaya, Nakornpathon. The animals were housed in the animal care facility at the Faculty of Pharmaceutical Sciences, Chulalongkorn University for 1-2 weeks before experimentation. Animals were housed under condition of controlled temperature of  $25 \pm 2$  °C and exposed to a daily 12 hours light-dark cycle. Animals were supplied with pellets diet from National Laboratory Animal Center and water ad libitum. This study was approved by Animal Ethic Committee of the Faculty of Pharmaceutical Sciences, Chulalongkorn University on the use of laboratory animals in teaching and research.

Rats were anaesthetized by ether and killed by cervical dislocation. The thoracic aorta was removed and placed in Petri-dish containing Krebs-Henseleit solution (KHS) of the following composition (mM): NaCl 118, KCl 4.7, CaCl<sub>2</sub> 2.52, MgSO<sub>4</sub> 1.64, KH<sub>2</sub>PO<sub>4</sub> 1.18, NaHCO<sub>3</sub> 7 and glucose 5.5. Then, the thoracic aorta was cleaned and cut in to 4 segments of approximately 0.3- 0.5 cm long. Each of ring segments was suspended in double walled organ baths (Harvard type Organ bath) and attached to an isometric force transducer (Harvard Apparatus Ltd.) under a resting tension of 1.0 g. The bath was contained 15 ml of KHS at 37°C and bubbled with a mixture of 95% O<sub>2</sub> and 5% CO<sub>2</sub>. The tension was recorded on model Gilson N<sub>2</sub> coupled to an amplifier (Harvard Apparatus Ltd, England). During an initial stabilization period of approximately 60 min, the solution was replaced every 15 min. The aortic rings were tested for functional endothelium by addition of acetylcholine (ACh 10 μM) after precontracted with phenylephrine (PE 10 μM). The relaxation of at least 60-80 % was considered endothelium intact for further experiment. In some preparations, the endothelium was removed by rubbing the lumen with a cotton swab. The absence of the functional endothelium was confirmed by a relaxant response of less than 10% after challenge with ACh (10 μM).

## Experiments

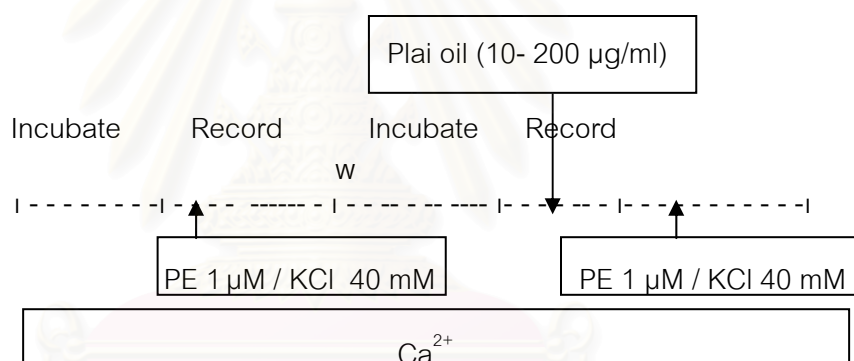

### 1. Effect of plai oil on aortic contraction

#### 1.1 Effect of plai oil on aortic contraction.

The aortic ring was placed in normal KHS until the tension was stable. Then, PE (1  $\mu$ M) or KCl (40 mM) was added to induce contraction. The tension was recorded for 20 minutes. The effects of Plai oil on PE- or KCl- induced contraction were determined by incubating plai oil at concentration of 10- 200  $\mu$ g/ml for 20 minutes prior to addition of either PE or KCl. Responses to each concentration of the plai oil were expressed as a percentage of the maximal contraction induced by either PE (1  $\mu$ M) or KCl (40 mM).

In separated experiments, the effect of terpinen - 4 - ol (34  $\mu$ g/ml) or sabinene (39  $\mu$ g/ml) on aortic contraction were also tested.

#### Experiment 1.1

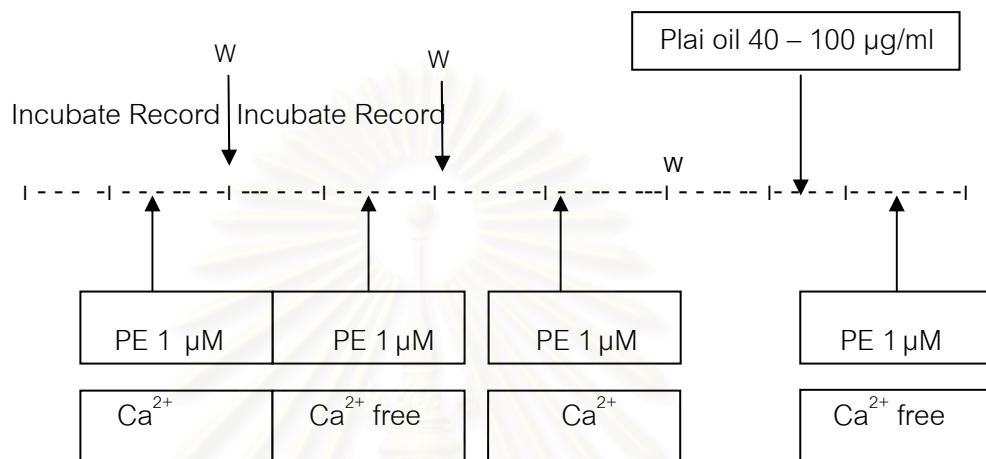

#### 1.2 Effect of plai oil on aortic contraction in calcium free medium.

##### 1.2.1 Contraction induced by phenylephrine

The aortic ring was placed in normal KHS until the tension was stable. The PE (1 $\mu$ M) was added to induce aortic contraction. The tension was recorded for 15 minutes. Then, the aortic ring was washed with Ca<sup>2+</sup>-free KHS 3 times, followed by incubating the ring in Ca<sup>2+</sup>-free KHS for 15 minutes prior to addition of PE (1 $\mu$ M). The effect of plai oil on PE-induced contraction in Ca<sup>2+</sup>-free KHS was studied by addition of plai oil 5 minutes prior to addition of PE. The response was expressed as a percentage of PE-induced contraction in Ca<sup>2+</sup>-free KHS in the absence of tested compounds

In separated experiments, the effect of terpinen - 4 - ol (34  $\mu\text{g/ml}$ ) or sabinene (39  $\mu\text{g/ml}$ ) on aortic contraction were also tested.

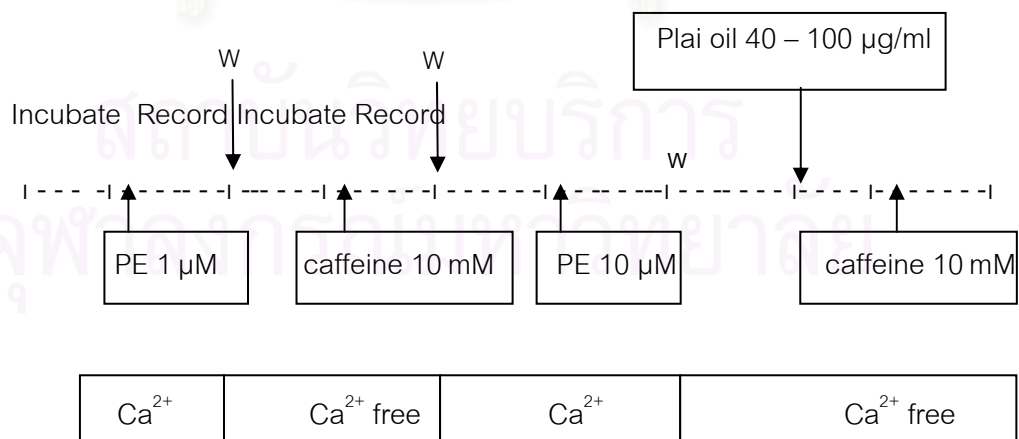

### Experiment 1.2.1

### 1.2.2 Contraction induced by caffeine

The experiment procedures were similar to those in section 1.2.1, except using caffeine (10 mM) instead of PE to induce contraction.

### Experiment 1.2.2

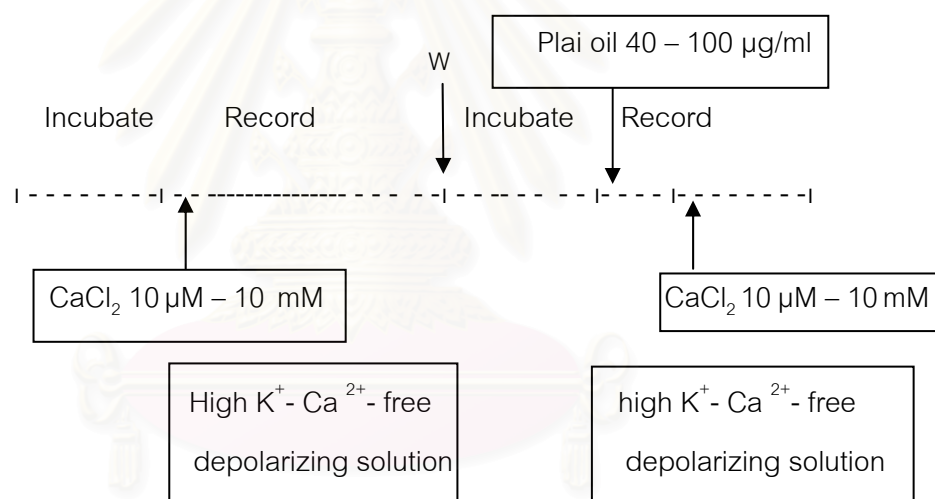

### 1.3 Effect of plai oil on contraction induced by $\text{Ca}^{2+}$ in high $\text{K}^+$ - $\text{Ca}^{2+}$ - free depolarizing solution

The aortic ring was placed in normal KHS until the tension was stable. After the equilibration period, the normal KHS was replaced by high  $\text{K}^+$  -  $\text{Ca}^{2+}$ - free depolarizing solution and incubated until the tension was stable. Then,  $\text{CaCl}_2$  (10  $\mu\text{M}$  to 10 mM) were added cumulatively to induce aortic contraction. The effect of plai oil was studied by addition of plai oil 5 minutes prior to  $\text{CaCl}_2$ . The contraction was expressed as a percentage of the maximum contraction induced by  $\text{CaCl}_2$ .

In separated experiments, the effect of terpinen - 4 - ol (34  $\mu\text{g}/\text{ml}$ ) or sabinene (39  $\mu\text{g}/\text{ml}$ ) on aortic contraction were also tested.

#### Experiment 1.3

## 2. Relaxant effects of plai oil

The aortic ring was placed in normal KHS until the tension was stable. The ring was precontracted with either PE (1  $\mu\text{M}$ ) or KCl (40 mM). When the contraction reached plateau state, plai oil (1.25  $\mu\text{g}/\text{ml}$  to 100  $\mu\text{g}/\text{ml}$ ) was added cumulatively to produce relaxation. The tension was recorded and expressed as a percentage of the PE - or KCl -induced contraction. In separated experiments, the effect of terpinen - 4 - ol ( $1.36 \times 10^{-3}$   $\mu\text{g}/\text{ml}$  to 136  $\mu\text{g}/\text{ml}$ ) or sabinene ( $1.36 \times 10^{-3}$   $\mu\text{g}/\text{ml}$  to 136  $\mu\text{g}/\text{ml}$ ) on aortic contraction were also tested.

In order to investigate the mechanism of plai oil on vasorelaxation, several specific inhibitors were added 30 minutes before the precontraction with PE. These inhibitors included atropine (1  $\mu\text{M}$ ), indomethacin (10  $\mu\text{M}$ ), tetraethylammonium (TEA) (10  $\mu\text{M}$ ), and propranolol (10  $\mu\text{M}$ ), L-NAME (10  $\mu\text{M}$ ), methylene blue (10  $\mu\text{M}$ ), or glibenclamide (10  $\mu\text{M}$ ). The relaxations were expressed as the percentage of the PE-induced contraction.

In separated experiments, the effect of terpinen - 4 - ol (13  $\mu\text{g}/\text{ml}$ ) or sabinene (15  $\mu\text{g}/\text{ml}$ ) on aortic contraction were also tested.

### Experiment 2.

### Statistical Data Analysis

Results were expressed as the mean  $\pm$  standard error of the mean (S.E.M) for 4-6 separated experiments. The EC50 was calculated from dose-response curves by linear regression. Statistical significances were tested either by one- way analysis of variance (ANOVA) followed by post-hoc Scheffer test. The  $p$  values of less than 0.05 were considered statistically significant.

$pD_2'$  value was calculated according to Van Rossum (1963).

$$pD_2' = -\log [B] + \log ([E_{AM}] / [E_{AMB}] - 1)$$

[B] was concentration of non competitive antagonist.

$[E_{AM}]$  and  $[E_{AMB}]$  were maximum contraction in the presence of antagonist and absence of antagonist.

## CHAPTER IV

### RESULTS

#### 1. Effect of oil from *Zingiber cassumunar* Roxb. (plai oil) on aortic contraction

##### 1.1 Effect of plai oil on aortic contraction in $\text{Ca}^{2+}$ -containing solution.

As demonstrated in Figure 4, the contraction profiles of endothelium-intact and endothelium-denuded aortic rings in response to PE were similar, consisting of phasic and tonic phases. The magnitude of tension induced by PE (1  $\mu\text{M}$ ) was  $0.990 \pm 0.024$  g ( $n = 37$ ) for endothelium-intact aortic rings, and  $0.867 \pm 0.021$  g ( $n = 40$ ) for endothelium-denuded aortic rings. The responsiveness of aortic rings toward PE in the presence of plai oil as well as its major constituents including terpinen-4-ol and sabinene was also shown in Figure 5 - 16. Pretreatment of the endothelium-denuded aortic rings with plai oil at concentration of 100 and 200  $\mu\text{g/ml}$  resulted in the significant decrease of contractile responses to PE by 26 % and 35 % ( $n = 6$ ), respectively (Figure 17). Plai oil inhibited the contraction effect of PE on aortic muscle in concentration-dependent manner. However, plai oil up to 200  $\mu\text{g/ml}$  had no significant inhibitory effect on PE-induced contraction of endothelium-intact aortic ring, suggesting the protective effect of endothelium. In the intact preparations, terpinen-4-ol (34  $\mu\text{g/ml}$ ) was more potent than plai oil (100  $\mu\text{g/ml}$ ) and sabinene (39  $\mu\text{g/ml}$ ) in suppressing PE-induced contraction. Terpinen-4-ol caused a significant reduction in PE - induced contraction by 21 % ( $n = 4$ ). In contrast, sabinene was the most potent compound in inhibiting PE-induced contraction in endothelium-denuded aortic ring (Figure 18).

The contraction profiles of aortic preparations in response to KCl (40 mM) were similar to those of PE-induced contraction, but with less magnitude (Figure 19). In this study, the aortic tension in response to KCl was  $0.867 \pm 0.021$  g ( $n = 27$ ) in endothelium-intact preparations and  $0.710 \pm 0.024$  g ( $n = 30$ ) in endothelium-denuded preparations. Plai oil was able to suppress KCl-induced contraction of both endothelium-intact and endothelium-denuded aortic rings in concentration-dependent manner (Figure 20 - 27).

In addition, the inhibitory action of plai oil was more potent against KCl-induced contraction than PE-induced contraction. At the concentrations of 50 and 100  $\mu\text{g/ml}$ , plai oil was able to suppress KCl - induced contraction of endothelium-intact aortic rings by 33 % and 58 %, respectively. However, an increase of concentration to 200  $\mu\text{g/ml}$  had no effect on the degree of inhibition, suggesting the maximum inhibitory effect of plai oil was 60% approximately. Removal of endothelium intensified the inhibitory effect of plai oil on KCl-induced contraction (Figure 28). At the concentration of 10 and 50  $\mu\text{g/ml}$ , plai oil significantly decreased the endothelium-denuded aortic contraction in response to KCl by 31 % and 51 %, respectively. The inhibitory effects of plai oil at the concentration of 10 and 50  $\mu\text{g/ml}$  were significantly higher in endothelium-denuded aortic preparation. Nevertheless, the maximum inhibitory actions of plai oil were quite comparable in endothelium-intact and endothelium-denuded preparations.

Furthermore, plai oil (at the concentration of 50 and 100  $\mu\text{g/ml}$ ) and sabinene (at the concentration of 39  $\mu\text{g/ml}$ ) significantly increased baseline tensions of endothelium-denuded aortic rings by  $28.31 \pm 6.18$  % ( $n = 8$ ),  $10.87 \pm 5.44$  % ( $n = 8$ ) and  $22.03 \pm 4.43$  % ( $n = 5$ ), respectively (Figure 10, 11, 16). These effects were not observed in endothelium-intact aortic rings (Figure 6, 7, 15), suggesting the influence of endothelium on vascular response to plai oil.

### 1.2 Effect of plai oil on aortic contraction in $\text{Ca}^{2+}$ -free medium.

In  $\text{Ca}^{2+}$ -free solution, PE (1  $\mu\text{M}$ ) and caffeine (10 mM) produced a small, transient contraction in endothelium-denuded (Figure 29, 33). The observable tensions were  $0.134 \pm 0.019$  g ( $n = 6$ ) for PE-induced contraction and  $0.051 \pm 0.017$  g for caffeine-induced contraction. In this study, plai oil (at concentration of 40  $\mu\text{g/ml}$  and 100  $\mu\text{g/ml}$ ) and sabinene (at concentration of 39  $\mu\text{g/ml}$ ) significantly inhibited PE-induced contraction whereas terpinen-4-ol (at concentration of 34  $\mu\text{g/ml}$ ) had no inhibitory effects (Figure 29, 30). The muscle tension decreased by 28 % ( $n = 6$ ) in the presence of plai oil at concentration of 40  $\mu\text{g/ml}$ . Plai oil at the concentration of 100  $\mu\text{g/ml}$  had not resulted in a significant increase in the inhibitory effect on PE-induced contraction in  $\text{Ca}^{2+}$ -free solution (Figure 31). In contrast to the effect of plai oil, upon increasing the concentration of sabinene to 39  $\mu\text{g/ml}$ , the inhibitory effect significantly increased by 36

% (Figure 32). Interestingly, the inhibitory actions of plai oil were not observed when caffeine, instead of PE, was a contractant. As shown in figure 33-34, plai oil at concentration of 100 µg/ml had no effect on caffeine-induced aortic contraction.

### 1.3 Effects of plai oil on contraction induced by addition of $\text{Ca}^{2+}$ in high $\text{K}^+$ - $\text{Ca}^{2+}$ -free depolarizing solution

The contraction profile of endothelium-denuded aortic rings upon cumulative addition of  $\text{CaCl}_2$  (10 µM to 10 mM) in high  $\text{K}^+$ - $\text{Ca}^{2+}$ -free depolarizing solution was shown in figure 35. Under this condition, plai oil at concentration of 50 and 100 µg/ml significantly shifted the dose response curve of  $\text{CaCl}_2$ -induced contraction rightward and downward (Figure 36). The maximum contractions of aortic muscles reduced to  $72.03 \pm 2.31$  % ( $n = 6$ ), and  $67.38 \pm 3.30$  % ( $n = 6$ ) in the presence of plai oil at concentration of 50 µg/ml and 100 µg/ml, respectively. In the presence of terpinen-4-ol (34 µg/ml) and sabinene (39 µg/ml), the maximum contractions of aortic muscles were  $102.51 \pm 3.01$  % ( $n = 6$ ), and  $38.19 \pm 3.77$  % ( $n = 6$ ), respectively (Figure 37). The apparent pD<sub>2</sub> values were  $3.76 \pm 0.09$  for plai oil at concentration of 50 µg/ml and  $3.57 \pm 1.35$  for plai oil at concentration of 100 µg/ml. The pD<sub>2</sub> values of terpinen-4-ol and sabinene were  $2.94 \pm 0.13$  and  $3.36 \pm 0.13$ , respectively.

## 2. Effects of Plai oil on the relaxation of rat aorta

### 2.1 Effects of plai oil on the relaxation of rat aorta precontracted with PE (10 µM) and KCl (40mM).

The relaxation profiles of endothelium-intact and endothelium-denuded aortic rings precontracted with PE (10 µM) were demonstrated in Figure 38-43. In this study, Plai oil (1.25-60 µg/ml) and terpinen-4-ol ( $1.36 \times 10^{-3}$  µg/ml to 136 µg/ml) were able to dose-dependently relax the vascular tensions of both endothelium-intact and endothelium-denuded aortic rings pretreated with PE (Figure 44-45). However, the vasodilation effects of plai oil and terpinen-4-ol were more prominent in endothelium-intact aortic rings than in endothelium-denuded preparations. Sabinene ( $1.36 \times 10^{-3}$  µg/ml to 136 µg/ml) elicited different relaxation profiles (Figure 42 - 43). Sabinene at the concentration up to 1.36 µg/ml was able to cause vasorelaxation of endothelium-intact aortic rings precontracted with PE. However, at the high concentration of more than 1.3

$\mu\text{g/ml}$ , sabinene induced contraction (Figure 45). This phenomenon was not observed in the experiment using endothelium-denuded aortic rings. As shown in Figure 42, sabinene at concentration of  $1.36 \times 10^{-3} \mu\text{g/ml}$  to  $136 \mu\text{g/ml}$  caused vasorelaxation of PE-precontracted rings in dose-dependent manner.

The apparent EC50 values for plai oil-induced relaxation were  $32.80 \pm 4.43 \mu\text{g/ml}$  ( $n = 6$ ) in endothelium-intact aortic rings and  $47.75 \pm 3.46 \mu\text{g/ml}$  ( $n = 6$ ) in endothelium-denuded aortic rings (Figure 44). Terpinen-4-ol at the highest concentration in this study ( $136 \mu\text{g/ml}$ ) caused  $34.44 \pm 3.80 \%$  ( $n = 6$ ) and  $73.92 \pm 9.72 \%$  ( $n = 7$ ) relaxation for endothelium-intact and endothelium-denuded aortic rings, respectively. Moreover, sabinene at the highest concentration in this study ( $136 \mu\text{g/ml}$ ) produced  $36.00 \pm 3.97\%$  vasorelaxation in endothelium-denuded aortic rings (Figure 45).

The relaxation profiles of endothelium-intact and endothelium-denuded aortic rings precontracted with KCl were shown in Figure 46-47. Plai oil ( $1.25$ - $60 \mu\text{g/ml}$ ) was able to produce vasorelaxation in both endothelium-intact and endothelium-denuded aortic rings precontracted with KCl. The apparent EC50 values of plai oil-induced vasorelaxation were  $29.05 \pm 6.78 \mu\text{g/ml}$  ( $n = 6$ ) in endothelium-intact aortic rings and  $36.42 \pm 5.66 \mu\text{g/ml}$  ( $n = 7$ ) in endothelium-denuded aortic rings (Figure 48).

## 2.2 The influence of endothelium on plai oil – induced relaxation.

In this study, plai oil ( $40 \mu\text{g/ml}$ ), terpinen-4-ol ( $13 \mu\text{g/ml}$ ), sabinene ( $15 \mu\text{g/ml}$ ) and mixture of terpinen-4-ol ( $13 \mu\text{g/ml}$ ) and sabinene ( $15 \mu\text{g/ml}$ ) were able to relax the vascular tensions of endothelium-intact aortic rings precontracted with PE ( $1 \mu\text{M}$ ) (Figure 49 – 50). At the concentration of  $40 \mu\text{g/ml}$ , plai oil caused  $33.18 \pm 2.84 \%$  ( $n = 18$ ) relaxation. Terpinen-4-ol ( $13 \mu\text{g/ml}$ ), sabinene ( $15 \mu\text{g/ml}$ ) and mixture of terpinen-4-ol ( $13 \mu\text{g/ml}$ ) and sabinene ( $15 \mu\text{g/ml}$ ) significantly different from plai oil induced relaxation at  $45 \pm 1.22 \%$  ( $n = 5$ ),  $5 \pm 0.70 \%$  ( $n = 5$ ), and  $29 \pm 0.33 \%$  ( $n = 5$ ), respectively (Figure 51). In contrast, the vasodilation in endothelium effects of plai oil was more prominent in endothelium-intact aortic rings than in endothelium-denuded preparations and terpinen-

4-ol, sabinene and mixture had not resulted in a significant induced relaxation effects on PE-induced contraction in endothelium-denuded aortic rings.

### 2.3 The endothelium-dependent relaxant mechanism of the Plai oil

The endothelium-dependent relaxation of plai oil reduced significantly in the presence of certain vasodilators including indomethacin, atropine, propranolol, glibenclamide, tetraethylammonium (TEA), L-NAME and methylene blue. In this study, plai oil at concentration of 40  $\mu\text{g}/\text{m}$  caused endothelium-dependent relaxation of  $33.18 \pm 2.84\%$  ( $n = 18$ ). The presence of indomethacin (10  $\mu\text{M}$ ), atropine (1  $\mu\text{M}$ ), propranolol (10  $\mu\text{M}$ ) and glibenclamide (10  $\mu\text{M}$ ) significantly reduced plai oil-induced relaxation (Figure 55-58). Atropine produced the highest inhibition of plai oil-induced relaxation by 97.59% in endothelium-intact aortic rings. In contrast, methylene blue (10  $\mu\text{M}$ ), L-NAME (10  $\mu\text{M}$ ) and tetraethylammonium (10  $\mu\text{M}$ ) exhibited less influence on plai oil-induced relaxation (Figure 52-54). Methylene blue was the less potent inhibitor of plai oil-induced relaxation. The relaxation reduced by 55.13 % in the presence of methylene blue endothelium-intact aortic rings (Figure 59).

The endothelium-independent mechanism of plai oil induced relaxation was also investigated. Plai oil at concentration of 40  $\mu\text{g}/\text{m}$  caused relaxation of endothelium-denuded aortic rings pretreated with PE at the magnitude of  $21.18 \pm 2.43\%$  ( $n = 17$ ). The results showed that neither of methylene blue, atropine, propranolol or glibenclamide could interfere plai oil-induced vasorelaxation in endothelium-denuded aortic rings (Figure 60-64).

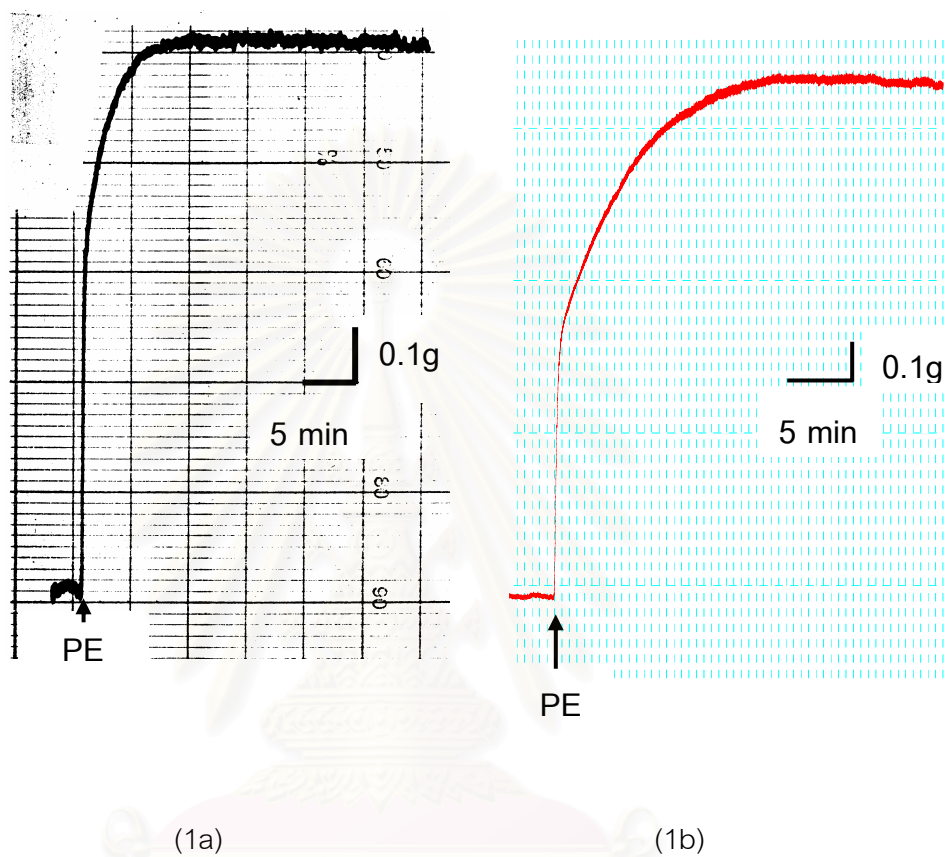

Figure 4 Representative tracing shows the PE-induced contraction of endothelium-intact aortic ring (1a) and endothelium-denuded aortic ring (1b) in  $\text{Ca}^{2+}$ -containing solution.

## CHAPTER V

### DISCUSSION AND CONCLUSIONS

This study aimed to investigate the action of oil from *Zingiber cassumunar* Roxb. (plai oil) on the modulating of vascular tone. The study was also designed to determine the influence of endothelium on the responsiveness of vascular smooth muscle to plai oil. As known, intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) is a key element in contraction of smooth muscle (Aronson, *et al.*, 2004; Karaki, *et al.*, 1997). The  $[\text{Ca}^{2+}]_i$  increases via a release of  $\text{Ca}^{2+}$  from internal store (Orallo, 1996; Komaru, 2000; Richard, 2002) as well as an influx of external  $\text{Ca}^{2+}$  through voltage-operated  $\text{Ca}^{2+}$  channel (VOC) and receptor-operated  $\text{Ca}^{2+}$  channel (ROC) (Kanmura, 1998); Marin, *et al.*, 1999; Sobey, 2001). Relaxation of smooth muscle is usually initiated by a decrease in  $[\text{Ca}^{2+}]_i$  via several mechanisms such as blockade of  $\text{Ca}^{2+}$  influx (Klabuade, 2005). In addition, endothelium plays a crucial role on vasorelaxation by releasing endothelium-derived relaxing factors (EDRF) such as nitric oxide (NO) (Luscher, 1995; Vanhoutte, 2004).

The result of this study demonstrated that plai oil had an intrinsic activity to influence vascular contractility. It was able to inhibit PE- and KCl-induced contraction of rat aortic rings in  $\text{Ca}^{2+}$ -containing solution. In the absence of endothelium, the inhibitory action of plai oil on PE-induced contraction was concentration-dependent. Endothelium appears to abolish the inhibitory effect of plai oil on PE-induced contraction. However, this observation was not evidenced in KCl-induced contraction. Plai oil elicited its concentration-dependent inhibition of both endothelium-intact and endothelium-denuded aortic rings in response to KCl although the effect of plai oil was more potent in the denuded preparation. Taken together, the inhibitory effects of plai oil were attenuated by the presence of endothelium. The results suggested the critical role of endothelium in protecting smooth muscle from plai oil effects. Unexpectedly, plai oil at concentration of 50 and 100  $\mu\text{g/ml}$  caused endothelium-denuded aortic rings to contract. This plai oil-induced contraction was unnoticeable in endothelium-intact rings. This phenomenon suggested the multi-action of plai oil on modulating the vascular tone.

It was possible that plai oil may directly affect the contraction of smooth muscle independent of endothelium.

Plai oil had the inhibitory effects on both PE- and KCl-induced contraction. Therefore it could be suggested that plai oil may directly disrupt the increase of  $[Ca^{2+}]_i$  in smooth muscle. It was possible that the actions of plai oil were mediated through nonspecific inhibition of  $Ca^{2+}$  influx from extracellular or to an inhibitory effect on intracellular  $Ca^{2+}$  release. To confirm these suggestions, the aortic contraction in the experimental model of  $Ca^{2+}$ -free medium and high  $K^+$ - $Ca^{2+}$ -free depolarizing solution were performed. In this study, plai oil was able to inhibit the PE-induced transient contraction in  $Ca^{2+}$ -free medium, but not the caffeine-induced contraction. In  $Ca^{2+}$ -free medium, the transient contraction of smooth muscle is largely attributed to  $Ca^{2+}$  release from sarcoplasmic reticulum (SR) (Gonzales, *et al.*, 2000). It has been well established that PE and caffeine, via their different mechanism, cause  $Ca^{2+}$  release from SR. The mechanism of PE-induced  $Ca^{2+}$ -release from SR is mediated through inositol triphosphate ( $IP_3$ ), which binds to its receptors on the SR and caused release  $Ca^{2+}$  (Gonzales, *et al.*, 2000; Abdel-Latif, 1986). The caffeine is ability to induce contractile response. Caffeine-induced a transient contraction is attributable to release of  $Ca^{2+}$  from SR (Gonzales, *et al.*, 2000; Karaki and Weiss, 1988; Watanabe, *et al.*, 1992). The mechanism of caffeine is considered to be due to its binding to the ryanodine receptor  $Ca^{2+}$ -release channel. This phenomenon occurs depleting intracellular  $Ca^{2+}$  store, that increases muscle tone and depolarizes the membrane (Marin, *et al.*, 1999). Hence, plai oil selectively inhibits  $Ca^{2+}$  release from SR via PE-mediated mechanism.

In high  $K^+$ - $Ca^{2+}$ -free depolarizing solution, this method was able to determine an inhibition of  $Ca^{2+}$  entry from extracellular pool when  $CaCl_2$  was added cumulatively. In this study, plai oil inhibited  $CaCl_2$ -induced contraction in a concentration-dependent manner. This finding suggests that plai oil directly affected  $Ca^{2+}$  influx across the membrane through VOC.

Furthermore, the present study was performed to investigate the mechanisms involved in plai oil-induced vasorelaxation. The results show that plai oil cause endothelium - dependent relaxation of aortic rings precontracted with PE and KCl. In addition, endothelium was significantly influenced on the actions of plai oil on vasorelaxation. It is possible that plai oil may cause endothelium to release its vasodilation factors such as NO. Consequently, these factors attenuate the contraction of vascular smooth muscle.

The potential mechanisms of plai oil-induced vasorelaxation were evaluated in endothelium-intact and endothelium-denuded aortic rings. In this study, the results demonstrated that endothelium significantly influenced on the actions of plai oil on vasorelaxation. Several mechanisms were probed for the relaxant effect of plai oil on endothelium cells, including NO-cGMP pathway, hyperpolarizing, cyclooxygenase, muscarinic receptors and  $\beta$ -adrenoceptor. NO is produced from L- arginine by NO syntase enzyme (Luscher, 1995). The presence of L-NAME, an inhibitor of NOS, abolished the vasorelaxant effect of plai oil, suggesting that plai oil exerted its vasorelaxation via an increase in NO production. Moreover, the presence of methylene blue, an inhibitor soluble guanylyl cyclase (sGC), (Wanstall, *et al.*, 2005), significantly inhibited the relaxation induced by plai oil. Taken together, the result confirmed that the relaxant effect of plai oil on rat aortic rings was mediated through NO-cGMP pathway.

The vasorelaxant activity of plai oil was mediated through multi-mechanisms. Hyperpolarizing factor was another potential mechanism determined in this study. The results demonstrated that glibenclamide, an ATP-sensitive potassium channel blocker, inhibited plai oil-induced relaxation (Parkington, *et al.*, 2004). In addition, the effect of plai oil was attenuated by tetraethylammonium chloride (TEA), a non selective-specific potassium channel inhibitor. Hence, plai oil may also cause vasorelaxation via hyperpolarizing mechanism. Furthermore, plai oil-induced relaxation was also attenuated by certain compounds including atropine, indomethacin and propranolol, suggesting the involvement of muscarinic receptor, cyclooxygenase and  $\beta$ -adrenoceptor.

Taken altogether, plai oil influenced vascular tone via several mechanisms. The actions of plai oil were integrative effect of each constituent in this mixture. Two major constituent of plai oil are terpinen-4-ol and sabinene. Other constituents include  $\alpha$  – terpinen,  $\gamma$  -terpinen,  $\alpha$ -pinen, and (E)-1-(3, 4-dimethoxyphenyl) butadiene (DMPBD) (Baker, and Nabney, 1975). This study demonstrated that terpinen-4-ol and sabinene had different actions on the vascular tone. In endothelium-denuded rings, sabinene was more potent than terpinen-4-ol against PE-induced contraction. In contrast, the action of sabinene in endothelium-intact rings was opposite to those of terpinen-4-ol. Moreover, both sabinene and terpinen-4-ol were able to cause endothelium independent relaxation of aortic smooth muscle, with less potency than plai oil. The reconstitution of sabinene and terpinen-4-ol did not increase its effects to the comparable degree of plai oil relaxant action. This result revealed the disparity between plai oil and its major constituents.

In conclusion, plai oil can modulate the vascular tone via endothelium dependent and endothelium independent pathways. Its direct actions on smooth muscle may be linked to non-specific inhibition of  $Ca^{2+}$  influx as well as inhibition of PE-mediated  $Ca^{2+}$  release from SR. Moreover, plai oil influences the vascular contractility through endothelium factors including NO-cGMP pathway, hyperpolarizing, cyclooxygenase, muscarinic receptors and  $\beta$ -adrenoceptor.

Table 3 The effect of plai oil on the percentage of contraction induced by PE (1 $\mu$ M) in endothelium-intact and endothelium-denuded.

	Endothelium-intact	Endothelium-denude
DMSO (0.07%)	100.89 $\pm$ 1.73	104.72 $\pm$ 2.24
Plai oil(10 $\mu$ g/ml)	100.71 $\pm$ 2.35	98.01 $\pm$ 2.25
Plai oil (50 $\mu$ g/ml)	92.85 $\pm$ 5.97	89.17 $\pm$ 1.88
Plai oil (100 $\mu$ g/ml)	90.79 $\pm$ 5.32	78.91 $\pm$ 1.89*
Plai oil (200 $\mu$ g/ml)	91.41 $\pm$ 3.14	69.46 $\pm$ 1.51*

Data were present as mean  $\pm$  S.E.M,  $n = 6$ .

\*  $p < 0.05$  showed significant difference of plai oil-treated group from DMSO 0.07% (v/v) group.

Table 4 The effect of plai oil (100  $\mu$ g/ml), terpinan-4-ol (34  $\mu$ g/ml) and sabinene (39  $\mu$ g/ml) on the percentage of contraction induced by PE (1  $\mu$ M) in endothelium-intact and endothelium-denuded aortic rings.

	Endothelium-intact	Endothelium-denude
DMSO 0.07% (v/v)	100.89 $\pm$ 1.73	104.72 $\pm$ 2.24
Plai oil (100 $\mu$ g/ml)	90.79 $\pm$ 5.32	78.91 $\pm$ 1.88*
Terpinan-4-ol (34 $\mu$ g/ml)	79.58 $\pm$ 2.15*	93.10 $\pm$ 0.96
Sabinene (39 $\mu$ g/ml)	90.60 $\pm$ 2.28	60.29 $\pm$ 3.14*

Data were present as mean  $\pm$  S.E.M,  $n = 4 - 6$ .

\*  $p < 0.05$  showed significant difference from DMSO 0.07% (v/v) group.

Table 5 The effect of plai oil on the percentage of contraction induced by KCl (40 mM) in endothelium-intact and endothelium-denuded.

	Endothelium-intact	Endothelium-denude
DMSO 0.07% (v/v)	99.37±1.51	96.96±3.16
Plai oil (10µg/ml)	100.49±3.42	66.32±1.83*
Plai oil (50µg/ml)	66.31±2.52*	45.86±2.32*
Plai oil (100µg/ml)	42.26±2.54*	42.42±1.83*
Plai oil (200µg/ml)	41.60±4.39*	44.23±2.36*

Data were present as mean ±S.E.M,  $n = 5 - 6$ .

\*  $p < 0.05$  showed significant difference of plai oil-treated group from DMSO 0.07% (v/v) group.

Table 6 The effect of plai oil (40µg/ml) and 0.07% (v/v) DMSO on the percentage of contraction induced by PE (1µM) and caffeine (10 mM) in endothelium-denuded aortic rings in Ca<sup>2+</sup>- free KHS.

Contractants	n	Plai oil (40 µg/ml)	Plai oil (100 µg/ml)	DMSO 0.07 % (v/v)
PE (1µM)	6	60.14±6.05 *	59.10±4.97 *	88.11.±7.5
Caffeine (10 mM)	6	114.12±6.78	105.18±4.94	108.20±7.25

Data were present as mean ±S.E.M, *n* = 6.

\* *p*<0.05 showed significant difference of contraction from DMSO 0.07% (v/v) group.

Table 7 The effect of plai oil (100 µg/ml), terpinan-4-ol (34 µg/ml) and sabinene (39 µg/ml) on the percentage of contraction induced by PE (1 µM) in endothelium-denuded aortic rings in Ca<sup>2+</sup>-free KHS.

	% Contraction
DMSO 0.07 % (v/v)	88.11±7.55
Plai oil (100 µg/ml)	59.10±4.97*
Terpinan-4-ol (34 µg/ml)	89.32±2.73
Sabinene (39 µg/ml)	51.70±2.70*

Data were present as mean ±S.E.M, *n* = 6.

\* *p*<0.05 showed significant difference of contraction from DMSO 0.07% (v/v) group.

Table 8 The percentage of contraction induced by adding cumulatively  $\text{CaCl}_2$  in endothelium-denuded aortic rings.

Concentration of $\text{CaCl}_2$ (M)	Control (n=10)	Plai oil 50 $\mu\text{g/ml}$ (n=6)	Plai oil 100 $\mu\text{g/ml}$ (n=6)	DMSO 0.07% (n=6)
$10^{-5}$	3.63 $\pm$ 0.87	3.38 $\pm$ 1.48	1.86 $\pm$ 0.77	4.82 $\pm$ 1.06
$5 \times 10^{-5}$	16.36 $\pm$ 2.40	8.67 $\pm$ 2.36	6.80 $\pm$ 2.51	24.56 $\pm$ 1.03
$10^{-4}$	33.12 $\pm$ 2.39	18.24 $\pm$ 3.15	14.50 $\pm$ 3.05	33.84 $\pm$ 1.03
$5 \times 10^{-4}$	54.04 $\pm$ 2.66	35.21 $\pm$ 2.75	31.15 $\pm$ 4.28*	52.78 $\pm$ 1.60
$10^{-3}$	70.03 $\pm$ 1.33	48.73 $\pm$ 2.36	42.56 $\pm$ 4.89*	65.11 $\pm$ 2.65
$5 \times 10^{-3}$	83.14 $\pm$ 1.08	59.86 $\pm$ 2.53	55.79 $\pm$ 3.36*	78.50 $\pm$ 2.86
$10^{-2}$	100 $\pm$ 0.00	72.03 $\pm$ 2.31*	67.38 $\pm$ 3.30*	96.76 $\pm$ 1.53

Data were present as mean  $\pm$ S.E.M,  $n = 6 - 10$ .

Table 9 The effects of plai oil (40 µg/ml), terpinan-4-ol (13 µg/ml) and sabinene (15 µg/ml) on percentage of induced relaxation in endothelium-intact and endothelium-denuded aortic rings.

	Endothelium-intact	Endothelium-denuded
Plai oil (40 µg/ml)	33.18±2.84	21.18±2.43 <sup>#</sup>
Terpinan-4-ol (13 µg/ml)	15.11±1.22 <sup>*</sup>	11.77±0.62
Sabinene (15 µg/ml)	1.79±0.70 <sup>*</sup>	13.81±1.32 <sup>#</sup>
Terpinan-4-ol + sabinene	4.33±0.33 <sup>*</sup>	15.70±0.53 <sup>#</sup>

Data were present as mean ±S.E.M,  $n = 6$ .

\*  $p < 0.05$  showed significant difference of contraction from plai oil group.

#  $p < 0.05$  showed significant difference of contraction from endothelium-intact.

Table 10 The effects of inhibitors on percentage of relaxation induced by plai oil (40 µg/ml) in endothelium-intact aortic rings.

	Mean of %relaxation	N
Plai oil (40 µg/ml)	33.18±2.84	18
Methylene blue (10µM)	14.89±4.35 <sup>*</sup>	5
Glibemclamide (10µM)	6.35±2.86 <sup>*</sup>	6
Indomethacin (10µM)	5.58±2.02 <sup>*</sup>	6
Atropine (1µM)	0.80±0.46 <sup>*</sup>	4
TEA (10µM)	13.46±1.44 <sup>*</sup>	5
Propranolol (10µM)	8.00±2.08 <sup>*</sup>	6
L-NAME (10µM)	3.79±1.26 <sup>*</sup>	5

Data were present as mean ±S.E.M,  $n = 4- 18$ .

\*  $p < 0.05$  showed significant difference of contraction from plai oil group.

Table 11 The effects of inhibitors on percentage of relaxation induced by plai oil (40  $\mu\text{g/ml}$ ) in endothelium-denuded aortic rings.

	Mean	N
Control plai oil (40 $\mu\text{g/ml}$ )	21.19 $\pm$ 2.43	17
Methylene blue (10 $\mu\text{M}$ )	17.80 $\pm$ 2.00	4
Glibenclamide (10 $\mu\text{M}$ )	12.60 $\pm$ 0.99	4
Atropine (1 $\mu\text{M}$ )	16.50 $\pm$ 0.42	4
Propranolol (10 $\mu\text{M}$ )	15.32 $\pm$ 2.76	4

Data were present as mean  $\pm$ S.E.M,  $n = 4 - 17$ .

## CURRICULUM VITAE

Mrs Rungnapa Mesripong was born in August 3, 1967 in Nan, Thailand. She graduated with a Bachelor of Science in Pharmacy in 2003 from Faculty of Pharmaceutical Sciences, Huachiew Chalermprakiet University, Thailand. She worked in Huachiew Chalermprakiet University, Thailand, for one year. In 2005, she started for the degree of Master of Science in Pharmacy in Chulalongkorn University, Thailand.
