**Computation of % viability**

$$\% \text{ viability} = \{[(b - a) / a] \times 100\} + 100$$

a = mean OD of control group

b = mean OD of test sample

If b higher than a, % viability = 100

#### Computation of % inhibition

$$\% \text{ inhibition} = [(a - b) / a] \times 100$$

a = mean OD of control group

b = mean OD of test sample

If b higher than a, % inhibititon = 0

#### Computation of $IC_{50}$ and $CC_{50}$

$IC_{50}$  is the concentration of sample which can reduce optical density by 50% compare with control group, calculated with probit/log transformation and regression (Finney, 1971) to produce the equation  $Y = a + bX$ ; when Y = probit value converted from % inhibition, X = log (concentration of sample in  $\mu\text{g/ml}$ ), a = intercept or the distance between X axis and the point where the regression line come across Y axis, and b = slope.

$CC_{50}$  is the concentration of sample which reduce optical density in MTT assay by 50% compare with control group, calculated as same as  $IC_{50}$  where as Y = probit value converted from % viability, X = log (concentration of sample in  $\mu\text{g/ml}$ )

#### Computation of Selectivity index

Selectivity index (SI) is ratio between  $CC_{50}$  and  $IC_{50}$ .
