WASIN PONCHEEWIN: AUTOMATIC CTR MEASUREMENT FROM CHEST RADIOGRAPH. ADVISOR: ASST. PROF. RAJALIDA LIPIKORN, Ph.D., 61 pp.

This research presents a method to automatically measure cardio-thoracic ratio (CTR) from a chest radiographic image using non-linear least square approximation and local minimum. The proposed method consists of initial boundary point identification, cardiac diameter measurement, thoracic diameter measurement and cardio-thoracic ratio measurement. First, the initial boundary points used to approximate the region of thoracic cavity are identified using general human anatomy features. Then the non-linear least square approximation and local minimum are used to detect the heart boundary. Finally, the thoracic cage boundary is detected and the cardio-thoracic ratio can be measured. The proposed method is tested on a set of 523 chest radiographs. The experimental results are evaluated using correlation test between two sets of numerical measurement which are measured by our proposed method and by the radiologists. The evaluation reveals that the correlation result on CTR is about 81%.

ACKNOWLEDGEMENTS

I would like to greatly thank Asst. Prof. Rajalida Lipikorn, Ph.D., my research advisor, for her guidance and encouragement which is an absolute impetus toward my study.

I am also honored to have Asst. Prof. Nagul Cooharajanone, Ph.D. and Suriya Natsupakpong, Ph.D. as my research chairman and committee.

Beside my advisor and committee, I would like to express my special thanks to Monravee Tumkosit, MD. and Petcharleeya Suwanpradit from Department of Radiology, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital for providing clinical advices and research data.

Additionally, this research is financially supported by Centre of Excellence in Mathematics (CEM), Thailand.

Finally, I would like to thank my family, especially my parents, and friends who always supported me throughout my study.

CHAPTER I

INTRODUCTION

The main purpose of this chapter is to briefly introduce about this research. It consists of objectives, scope of work, problem formulation and the expected outcome of the experiments.

Radiography is one of the most widely used medical procedures performed to diagnose the insight of human body. Chest radiograph is a useful tool for diagnosing the abnormality that occurs in chest cavity and also a source to obtain the size of the heart which is one of the most important factors used to indicate many heart diseases including enlarged heart or cardiomegaly [1]. In the past, cardio-thoracic ratio (CTR) was manually measured by radiologists. At the present, computer-aided diagnosis (CAD) system has become much more popular. This technology has improved the way to diagnose many diseases by giving many advantages such as accuracy, time consumption reduction and automation [2] but a fully automated cardio-thoracic ratio (CTR) measurement has not yet been able to gain a complete reliability from radiologists.

The aim of this research is to propose a new method that can fully automate the cardio-thoracic ratio (CTR) measurement without the use of training data set which can improve accuracy and efficiency.

1.1 Objectives

- 1) To detect the heart and boundary of the heart.
- 2) To automatically display cardio-thoracic ratio (CTR) which is the proportion between the widest part of the heart and the widest part of the thoracic-cage.

1.2 Scope of Work

In this study, the proposed method is constrained as follows:

- 1) Only Digital Imaging and Communications in Medicine (DICOM) file format is allowed as an input image.
- 2) Only Posterior-Anterior (PA) radiographs are allowed.

- 3) Input images must be able to be analyzed by radiologists.
- 4) Input images must have high contrast.

1.3 Problem Formulation

Although, cardio-thoracic ratio (CTR) measurement is commonly performed in radiograph by a radiologist for a long time but even with today's technologies, an automatic procedure still not yet a common tool to use in diagnosis process due to an unreliable results.

However, the measurement made by a radiologist could possibly result in individual variation and time consuming. Therefore, automatic system with high accuracy rate will be a solution for this problem.

1.4 Expected Outcomes

- 1) The method that can measure cardio-thoracic ratio (CTR) from chest radiograph automatically.
- 2) The method that reduces time complexity and man power.
- 3) The method that increases the accuracy and efficiency of the automated diagnosis.

CHAPTER II

FUNDIMENTAL KNOWLEDGE AND LITERATURE REVIEW

This chapter provides a fundamental knowledge about the technique used in the proposed method and also describes related work in the literature review section to give better understanding about this work.

2.1 Fundamental Knowledge

2.1.1 Digital Imaging and Communication in Medicine (DICOM)

DICOM is a standard format for handling, storing, printing and transmitting information in a medical image. It contains all the information about a patient within the file such as name, ID, age and etc. which are called attributes.

2.1.2 Histogram Equalization

This method enhances the contrast of an image by transforming intensity values of an image so that the histogram of the output image is distributed evenly as shown in Figure 1.

Figure 1 Histogram equalization

2.1.3 Median Filtering

This filtering technique is used to remove noise from an image. It is performed on an image by ranking the intensities of all pixels in an $m \times n$ neighbor and replacing the center pixel's intensities with the median intensity.

For example:

Using 3x3 filter

4	3	5
3	10	5
4	2	5

Figure 2 Original intensities within median filter.

The original intensities in the neighbor under the filter are as shown in Figure 2 and it's ranked in ascending order as 2, 3, 3, 4, 4, 5, 5, 5, 10.

The median value within the filter is 4 thus the value of the center pixel in the filter will be changed to 4 as shown in Figure 3:

4	3	5
3	4	5
4	2	5

Figure 3 Modified intensity with median filter.

2.1.4 Density-Based Spatial Clustering of Application with Noise (DBSCAN)

DBSCAN is a data clustering algorithm [3]. It is based on the concept of density-reachability. It is an idea of whether point B can be directly searched from point A under the condition that it is not within a given distance. Figure 4 shows that points B and C are density-reachable by point A, which is a core point, and thus they are density-connected and belong to the same cluster while point N is not reachable, therefore, it will be defined as noise.

Figure 4 DBSCAN

<http://en.wikipedia.org/wiki/DBSCAN>

Data is separated into groups by using the minimum distance between each points and the minimum number of points required to form a dense region as parameters.

2.1.5 Polynomial Curve Fitting

Curve fitting is used to find the best fit curve from a given dataset. In this work, polynomial curve fitting is used to estimate the boundary on both sides of the heart from the given dataset consisting of points which are retrieved from the gradient procedure. Examples of polynomial curve fitting of 2nd degree and 4th degree are shown in Figure 5.

Figure 5 Example of polynomial curve fitting

The curve of the estimate line is based on the degree used in the polynomial equation as follows:

Let $f(x, y)$ represent an input image where (x, y) are the coordinates of each pixel and $f(x)$ be an intensity of any pixel from each column of an image. The polynomial equation is written as:

$$f(x) = c_1x^n + c_2x^{n-1} + \dots + c_nx + c_{n+1} \quad (1)$$

where n is the degree of the polynomial equation and c_j is the coefficient value of the polynomial which can be calculated from

$$\sum_{k=1}^{n+1} (\sum_{i=1}^M x_i^{2n+2-j-k}) c_j = \sum_{i=1}^M x_i^j f(x_i) \quad (2)$$

Deviation of the intensity curve from each data point is

$$e_i = f(x_i) - p(x_i), i = 1, \dots, M \quad (3)$$

where M is the number of pixels in each column. By using least square error, $\frac{\partial E}{\partial c_j} = 0, j = 1, \dots, n + 1$ such that E is the sum of the squared deviation:

$$E = \sum_{i=1}^M e_i^2$$

2.1.6 Pearson's Linear Correlation Coefficient

Pearson's correlation coefficient is a measure of the linear correlation between two variables X and Y , giving a value between +1 and -1, where 1 is a positive correlation, 0 is no correlation, and -1 is a negative correlation as shown in Figure 6.

Figure 6 Pearson's linear correlation coefficient

The formula is

$$p(x, y) = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sqrt{\sum(x - \bar{x})^2 \sum(y - \bar{y})^2}}$$

where $p(x, y)$ is a correlation result, \bar{x} and \bar{y} are the sample means of x in dataset 1 and y in dataset 2, respectively .

2.2 Literature Review

Various techniques to create a computer-aided diagnosis (CAD) in chest radiograph have been proposed. Related work about cardiomegaly detection and cardio-thoracic ratio (CTR) measurement is the main focus. The study by M. Ilovar and L. Šajn uses average intensity and image blurring for image initiation then uses edge detection to locate the position of the heart. After finding the widest part of the heart, the horizontal line is drawn outward from the heart boundary to each boundary of the image and identify the widest part of the thoracic cage by locating the brightest intensity from each side of the body [4]. However, this method of measuring the CTR is not precise according to the actual definition by Danzer, C.S. [5]. Ha Dai Duong and Dao Thanh had developed a segmentation algorithm using texture-based results in a rough estimation of three areas: dark region, gray region and light region which are not yet suitable for cardio-thoracic ration (CTR) measurement due to precision matters [6]. Ishida and his colleagues developed an algorithm that uses histogram analysis and edge detection technique with feature analysis to diagnose the cardiomegaly but the region of interest (ROI) which is used in histogram analysis is manually selected [7]. Another excellent work has been proposed by Samuel G. Armato III and his colleagues which uses iterative global and local histogram analysis to determine the proper threshold value used for the chest radiograph but the region of interest (ROI) which is used in histogram analysis is also manually selected and the evaluation method was unreliable due to radiologist ranking [8]. Another novel method was developed by Sezaki Nobuhiko and Ukena Kohji which can compute the cardio-thoracic ratio (CTR) with good results and complexity but it must be installed on their special instrument [9]. Beside all of the technical work, there are a survey and a comparative study of other proposed methods that provide useful information [10, 11]. The survey gives information about existing techniques that have been used in computer-aided diagnosis (CAD) in chest radiograph. The content was separated into three sections: enhancement, segmentation (e.g. lung fields, rib cage) and analysis (e.g. size measurement, lung nodule detection, texture analysis) [10]. A comparative study in segmentation focused on three methodologies: active shape models (ASM), active appearance

models (APM) and pixel classification (PC). These methodologies need training data in order to create a landmark and an initial model used within algorithms. It surely yields a good result in segmentation but not better than other algorithms without a model or training data. Therefore, those methodologies are not appropriate candidates for this work [11].

CHAPTER III

PROPOSED METHODOLOGY

The proposed methodology uses non-linear least square approximation and local minimum to measure cardio-thoracic ratio (CTR) automatically from chest radiograph. It consists of the following steps (as shown in Figure 7):

- 1) Perform image pre-processing.
- 2) Identify Initial boundary points.
- 3) Measure cardiac and thoracic diameters.
- 4) Calculate the cardio-thoracic ratio (CTR).

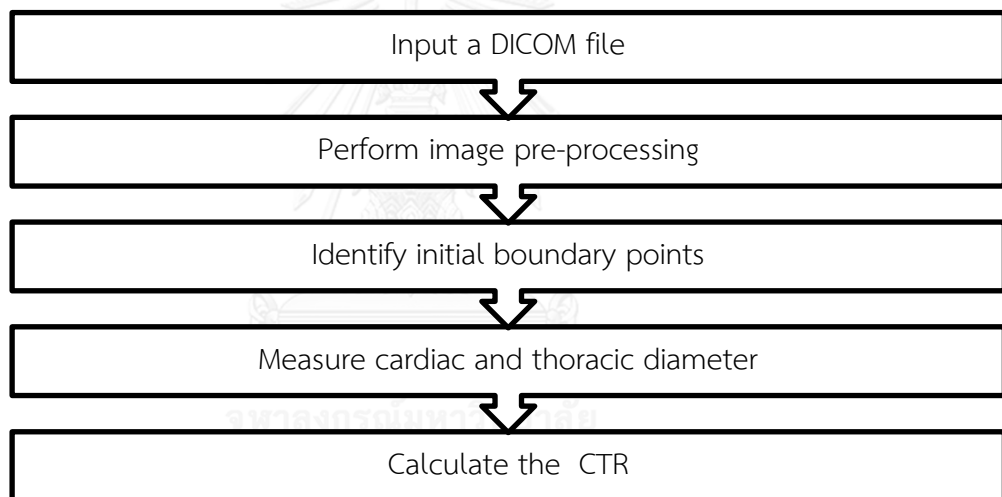

Figure 7 Work process of the proposed methodology

3.1 Image Pre-processing

The original DICOM files, obtained from an X-Ray machine with all constraints as mentioned in the scopes of work, are used as input images. Each image is resized and converted to JPEG file format. The visibility of the organs in each image is enhanced by using histogram equalization and median filter. Then, the average intensity of the processed image is calculated and used as threshold value to convert the original gray scale image to a binary image as shown in Figures 8, 9, 10 and 11.

Figure 8 Original DICOM file

Figure 9 Using histogram equalization

Figure 10 Using median filter

Figure 11 Binary image

3.2 Initial Boundary Point Identification

In this step, the initial region of lung is identified by:

- 1) Identify the initial center point of the body.
- 2) Identify the initial left and right boundary points of the lung.
- 3) Identify the initial upper and lower boundary points of the lung.

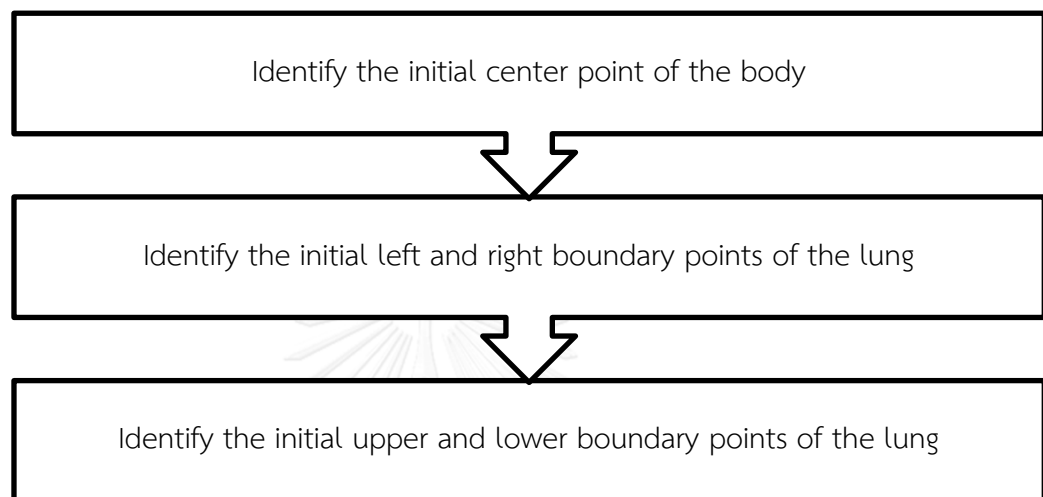

Figure 12 Initial boundary point identification process

3.2.1 The Initial Center Point of the Body Identification

This point is identified by setting the x-coordinate to equal to the middle column of the white region on the last row of a binary image obtained from the previous step of each patient which is assumed to represent the patient's body and setting the y-coordinate to be half of the height of an image as shown in Figure 13. This point is shown as '*' in Figure 17.

Figure 13 Initial center point of the body Identification

3.2.2 The Initial Left and Right Boundary Points of the Lung Identification

These points are identified by using the y -coordinate of the initial center point of the body as a reference row to find any pixels along the same row whose gradients of intensity are not equal to 0 by calculating outward from the y -coordinate of the initial center point of the body as shown in Figure 14.

Figure 14 Selected row

These gradients might occur more than what is expected so the selection is constrained as follows:

- First gradient that occurs from the boundary of an image.
- First and second gradients that occur from the initial center point of the body.

The procedure is represented in Figure 15.

Figure 15 Selected gradient

The proper gradients are defined as the initial left and right boundary points.

There are altogether six boundary points which represent the left and the right boundaries. Four pixels represent the left and the right boundaries of each lung and two pixels represent the left and the right boundaries of the body. These points are shown as '+' in Figure 17.

3.2.3 The Initial Upper and Lower Boundary Points of the Lung Identification

These points are identified by finding the upper and the lower y-coordinates of the midpoints between the left and the right boundary points of both sides of the lung whose gradients are not equal to 0. The upper boundary point is defined at the lower of the upper y-coordinates of both sides of the lung and the lower boundary point is defined at the lower y-coordinate of the right lung only because the heart at the left lung might interfere the result as shown in Figure 16.

Figure 16 Initial upper and lower boundary points of the lung Identification

These points are shown as 'x' in Figure 17.

Figure 17 Final results of initial boundary point identification

3.3 Cardiac and Thoracic Diameter Measurement

Since the cardio-thoracic ratio is computed by dividing the cardiac diameter (CD) by the thoracic diameter (TD), the next process is to measure the cardiac diameter. Because the heart is non-rigid and asymmetry, the proposed cardiac diameter measurement divides the heart into two sides: the left and the right. It then finds the widest part of the heart on the left and the widest part of the heart on the right separately. The summation of these two values becomes the cardiac diameter. In order to find the widest parts on each side of the heart, the proposed cardiac diameter measurement computes the maximum distances from the center of the body which are the vertical lines that pass through the initial center point of the body to the left side and the right side of the heart.

3.3.1 Measurement on the Left Side of the Heart

- Extract the region of the whole thoracic cage from the enhanced gray scale image by using the initial upper, lower, left and right boundary points obtained from 3.3.2. The extracted region is shown in Figure 18(a).
- Extract the region of the left thoracic cage by segmenting the left side of the thoracic cage from the previous step. The extracted region is shown in Figure 18(b).

(a) Whole thoracic cage

(b) Left thoracic cage

Figure 18 Extracted region of the left side of the heart

- Compute the average intensity of the whole thoracic cage and the average intensity of the left thoracic cage. Set the threshold value to equal to the minimum average intensity from these two values.
- Convert an image of the left thoracic cage to a binary image using the threshold value previously obtained.
- Detect the boundary on the left side of the heart by scanning along the vertical line that passes through the IC point to find the first pixel whose gradient is not equal to 0.
- Detect the left boundary of the heart by using Density-based spatial clustering of applications with noise (DBSCAN) [9] to remove noise from the boundary.
- Connect the left boundary of the heart by using non-linear least square approximation as shown in equations. (1), (2) and (3).

$$E = \sum_{i=1}^m [y_i - P_n(x_i)]^2 \quad (1)$$

where $P_n(x_i)$ is a polynomial equation, y_i are data and E represents the sum of errors of m data which consists of x_i, y_i when $i = 1, 2, \dots, m$.

$$\frac{\partial E}{\partial a_j} = 0 \quad (2)$$

In order to minimize the sum of the least square, the gradient is set to zero where a_j are the coefficients of a polynomial $P(x)$ of degree n , $j = 1, 2, \dots, n$, and the results will be used in equation (3).

$$P_n(x) = a_0 + a_1x + \dots + a_{n-1}x^{n-1} + a_nx^n \quad (3)$$

- Find the widest part on the left side of the heart by finding the maximum distance along the vertical line from the center of the body to the left boundary of the heart. The left boundary and its widest part, LCD, are shown in Figure 19.

Figure 19 Widest part on the left side of the heart

3.3.2 Measurement on the Right Side of the Heart.

- Extract the region of the right thoracic cage from the enhanced gray scale by using the initial upper, lower, left and right boundary points obtained from 3.3.2. The extracted region is shown in Figure 20.

Figure 20 Extracted region on the right side of the heart

- Quantize an 8-bit gray scale image of the right thoracic cage to a 4-bit gray scale image and plot a histogram.
- Find the valley in the histogram whose area is the maximum. The area can be computed by

$$valley = \int_a^b (c - f(x)) dx \quad (4)$$

where $f(x)$ is an equation of the graph, c represents the highest point of the valley and $[a, b]$ represent the range of intensity of the valley. Then the threshold value, t , is set to equal to the intensity of the local minimum of the valley as shown in Figure 21.

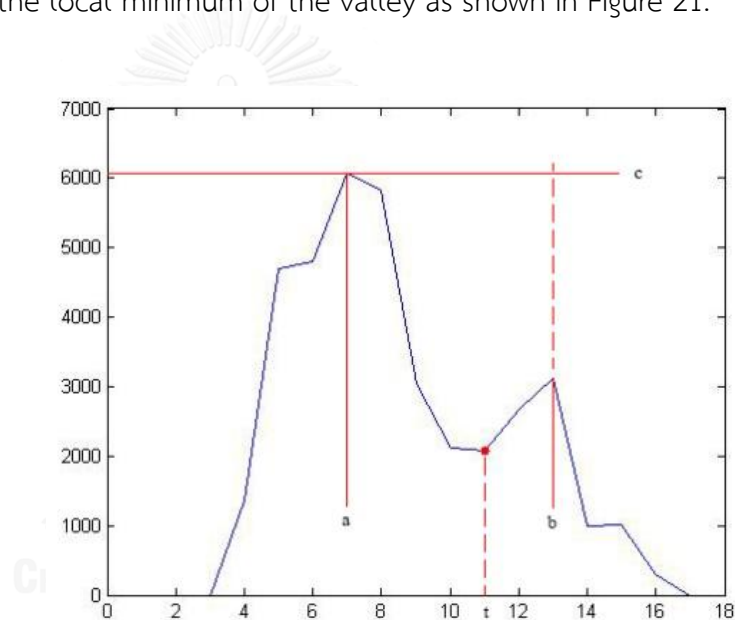

Figure 21 Local minimum calculation

- Convert an image of the right thoracic cage to a binary image using the threshold value previously obtained.
- Detect the right boundary of the heart by using DBSCAN to remove noise from the boundary.
- Connect the right boundary of the heart by using the same non-linear least square approximation.
- Find the widest part on the right side of the heart by finding the maximum distance along the vertical line from the center of the

body to the right boundary of the heart. The right boundary and its widest part, RCD, are shown in Fig. 22.

Figure 22 Widest part on the right side of the heart

3.3.3 Thoracic Diameter Measurement.

The diameter of the thoracic is measured from a binary image by calculating the distance from the left to the right boundary of the thoracic cage along each row. The maximum diameter, TD, is shown in Figure 23.

Figure 23 Maximum diameter of Thoracic cage

Next, the cardio-thoracic ratio (CTR) can be calculated by

$$CTR = \frac{CD}{TD} \quad (5)$$

where $CD = LCD + RCD$ as shown in Figure 24.

Figure 24 Cardio-Thoracic ratio calculation process

CHAPTER IV

EXPERIMENTAL RESULTS AND DISCUSSION

The proposed method was tested on a set of 523 chest radiographs which were taken in posterior-anterior position. All images are collected from King Chulalongkorn Memorial Hospital, Bangkok, Thailand. The format of the original images is DICOM format with the resolution of 2688x2208 pixels.

To validate efficiency of our work, a correlation test using Pearson's linear correlation coefficient is performed between our results and set of numerical measurement results. The first set consists of RCD, LCD, CD, TD and CTR which were measured by the radiologist and the second set which contains the same type of information but were measured by our proposed technique. The correlation results are demonstrated in Table 1.

Table 1 Correlation test results

RCD	LCD	CD	TD	CTR
0.842	0.9018	0.8909	0.9389	0.8129

The comparison results which are used to perform correlation test are displayed in graphs shown in Figures 25, 26, 27, 28 and 29. Also some examples of the result images are displayed in Table 2 and they indicate that the points used to measure cardio-thoracic ratio (CTR) selected by radiologist and the proposed method yield similar numerical results.

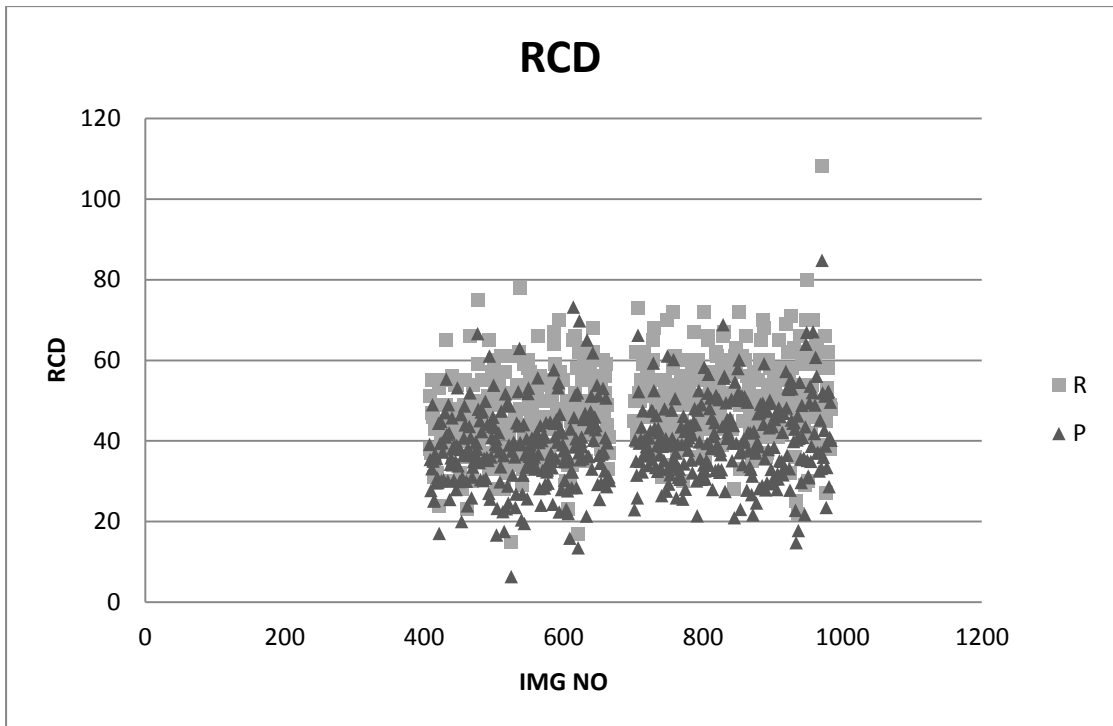

Figure 25 RCD comparison graph

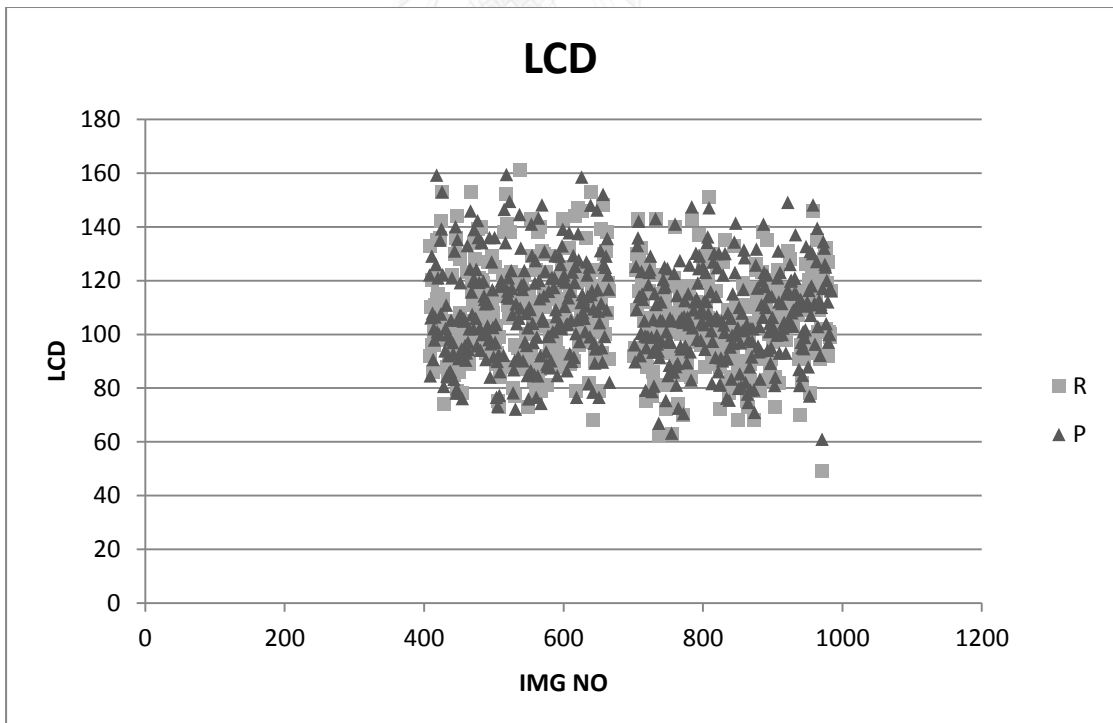

Figure 26 LCD comparison graph

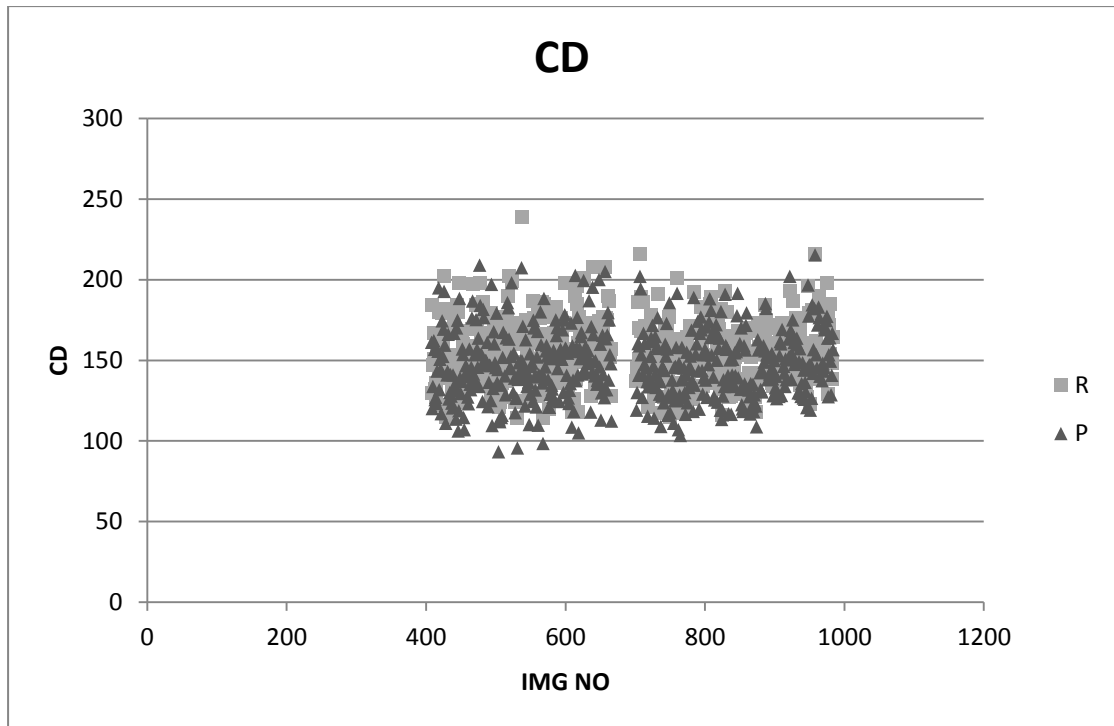

Figure 27 CD comparison graph

623		
634		

From an observation in the correlation test results in Table 1, the promising outcomes of the proposed method are shown. However it is not yet 100 percent perfect in analyzing or diagnosing the cardio-thoracic ratio (CTR) of the patient due to several reasons. First of all, the points used as a reference data to calculate the cardio-thoracic ratio (CTR) which are pinned by the radiologist are an individual skill thus even for the same chest radiograph but if it is analyzed by different radiologist, the position of the pinned points will be slightly different. Secondly, some of the chest radiographs contain pericardial fat pad or vascular shadow whose intensity values are close to the intensity values of the heart which makes the diagnosis process more intricate and likely to result in an incorrect measurement of the overall data especially in RCD as shown in IMAGE NO: 596, 456, 613, 623 and 634 displayed in Table 2.

CHAPTER V

CONCLUSION

This thesis presents a new method to automatically measure the cardio-thoracic ratio (CTR) from an input image of a Posterior-Anterior chest radiograph by using non-linear least square approximation and local minimum. Then, Pearson's linear correlation coefficient is used to validate the results between two measurements, one from the radiologist and another one from the proposed method, displayed in Table 1. In Table 1, the correlation results of right cardiac diameter (RCD), left cardiac diameter (LCD), cardiac diameter (CD), thoracic diameter (TD) and cardio-thoracic ratio (CTR) measurement show quite a promising trend between two numerical datasets which strongly supported by the example of comparison results demonstrates in Table 2. However, these results can be improved due to some of an incorrect measurement because some of the chest radiographs might contained pericardial fat pad or vascular shadow whose intensities are similar to the heart which is difficult to distinguish and cause the measurement of RCD and LCD to be discrepancy.

For future work, the machine learning and the artificial neural network might be needed in order to increase the correlation results but this procedure may take more time consumption than this proposed methodology.

Abstract

This paper presents a method to automatically measure cardio-thoracic ratio (CTR) from a chest radiographic images using non-linear least square approximation and local minimum. The proposed method consists of initial boundary point identification, cardiac diameter measurement, thoracic diameter measurement and cardio-thoracic ratio measurement. First, the initial boundary points used to approximate the region of thoracic cavity are identified using general human anatomy features. Then the non-linear least square approximation and local minimum are used to detect the heart boundary. Finally, the thoracic cage boundary is detected and the cardio-thoracic ratio can be measured. The proposed method is tested on a set of 255 chest radiographs. The experimental results are evaluated using correlation test between two sets of numerical measurement which are measured by our proposed method and by the radiologists. The evaluation reveals that the correlation result on CTR is about 78%.

Keywords: Chest radiograph, cardio-thoracic ratio, computer-aided diagnosis.

1. Introduction

Radiography is one of the most widely used medical procedures performed to diagnose the insight of human body. Chest radiograph is a useful tool for diagnosing the abnormality that occurs in chest cavity and also is a source to obtain the size of the heart which is one of the most important factors used to indicate many heart diseases including enlarged heart or cardiomegaly [1]. In the past, cardio-thoracic ratio (CTR) was manually measured by radiologists. At the present, computer-aided diagnosis (CAD) system has become much more popular. This technology has improved the way to diagnose many diseases by giving many advantages such as accuracy, time consumption reduction and automation [2] but a fully automated CTR measurement has not yet been able to gain a complete reliability from radiologists.

Various techniques of automated detection of cardiomegaly have been proposed. The study by M. Ilovar and L. Šajn uses edge detection to locate the position of the heart and determine the border of the thoracic cage by drawing a horizontal line toward the end of an image from the points on both sides of the heart boundary which have been calculated as the widest part and finding the brightest intensity [3]. This method of measuring the CTR is not precise according to the actual definition by Danzer, C.S. [4]. Ishida and his colleagues had developed an algorithm that uses histogram analysis and edge detection technique with feature analysis to diagnose the cardiomegaly but it is not yet fully automated [5]. Another novel method was developed by Sezaki Nobuhiko and Ukena Kohji which can compute the CTR within one second but it must be installed on their special instrument [6]. Beside all of the technical work, there are also a survey and a comparative study of other proposed methods that provide useful information [7,8].

The aim of this proposed method is to develop a fully automated CTR measurement technique without the use of training data set which can improve the accuracy and efficiency. The paper is organized as follows: section 2 presents related work and theoretical background, section 3 proposes a new CTR measurement, section 4 provides experimental results, and section 5 gives some discussion and conclusions.

2. Proposed methodology

In order to measure CTR, the radiographic images in DICOM format are converted to gray scale images. The input images are then passed through the proposed method which consists of four main processes: initial boundary point identification, cardiac diameter measurement, thoracic diameter measurement, and CTR measurement.

2.1 Initial boundary point identification

In the first process, histogram equalization and median filter are used to enhance a gray scale image. Then, the average intensity is used as a threshold value to convert a gray scale image to a binary image. Next, the initial boundary points which are used to define the region of lung are identified by the following process.

i) Identify the initial center point (IC) of the body by setting the x-coordinate to equal to the middle column of the white region on the last row of a binary image of each patient which is assumed to represent the patient's body and setting the y-coordinate to be half of the height of an image. The IC point is shown as '*' in Fig. 1.

ii) Identify the initial left and right boundary points (LR) by using the initial center point obtained from previous step. There are altogether six boundary points which represent the left and the right boundaries. Four pixels represent the left and the right boundaries of each lung, and two pixels represent the left and the right boundaries of the body. These six initial boundary points are identified

by finding the pixels along the same row as the initial point whose gradients of intensity are not equal to 0. The LR points are shown as '+' in Fig. 1.

iii) Identify the initial upper and lower boundary points (UL) of the lung by finding the lower and upper y-coordinates of the midpoint between the left and the right boundary points of the lung whose gradients are not equal to 0. The UL points are shown as 'x' in Fig. 1.

Fig 1: Initial boundary points.

2.2 Cardiac Diameter Measurement

Since the cardio-thoracic ratio is computed by dividing the cardiac diameter (CD) by the thoracic diameter (TD), the next process is to measure cardiac diameter. Because the heart is non-rigid and asymmetry, the proposed cardiac diameter measurement divides the heart into two sides: the left and the right. It then finds the widest part of the heart on the left and the widest part of the heart on the right separately. The summation of these two values becomes the cardiac diameter. In order to find the widest parts on both sides of the heart, the proposed CD measurement computes the maximum distance from the center of the body which is a vertical line that passes through the IC point to the left side of the heart and the maximum distance from the center of the body to the right side of the heart as follows:

2.2.1 Measurement on the left side of the heart

i) Extract the region of the whole thoracic cage from an image by using the initial boundary points (LR and UL points) obtained from the first process. The extracted region is shown in Fig. 2(a).

ii) Extract the region of the left thoracic cage by segmenting the left side of the thoracic cage from the previous step. The extracted region is shown in Fig. 2(b).

iii) Compute the average intensity of the whole thoracic cage and the average intensity of the left thoracic cage. Set the threshold value to equal to the minimum average intensity from these two values.

iv) Convert an image of the left thoracic cage to a binary image using the threshold value obtained from step 3).

v) Detect the boundary on the left side of the heart by scanning along the vertical line that passes through the IC point to find the first pixel whose gradient is not equal to 0.

vi) Detect the left boundary of the heart by using Density-based spatial clustering of applications with noise (DBSCAN) [9] to remove noise from the boundary.

vii) Connect the left boundary of the heart by using non-linear least square approximation as shown in eqn. (1), (2) and (3).

$$E = \sum_{i=1}^m [y_i - P_n(x_i)]^2 \quad (1)$$

where E represents the sum of error of m data which consists of x_i, y_i when $i = 1, 2, \dots, m$.

$$\frac{\partial E}{\partial a_j} = 0 \quad (2)$$

In order to minimize the sum of the least square, the gradient is set to zero where a_j is the coefficients of a polynomial $P(x)$ of degree $n, j = 1, 2, \dots, n$, and the results will be used in eqn.(3).

$$P_n(x) = a_0 + a_1x + \dots + a_{n-1}x^{n-1} + a_nx^n \quad (3)$$

viii) Find the widest part on the left side of the heart by finding the maximum distance along the vertical line from the center of the body to the left boundary of the heart. The left boundary and its widest part, LCD, are shown in Fig. 2(c).

(a) The thoracic cage. (b) The left thoracic cage. (c) The left boundary of the heart and the widest part.

Fig. 2: The thoracic cage, the left thoracic cage and the left boundary of the heart and the widest part.

2.2.2 Measurement on the right side of the heart

i) Extract the region of the right thoracic cage by using the initial boundary points (LR and UL points) obtained from the first process. The extract region is shown in Fig. 3.

ii) Quantize an 8-bit gray scale image of the right thoracic cage to a 4-bit gray scale image and plot a histogram.

(a) The right thoracic cage.

(b) Histogram of the right thoracic cage.

Fig 3: The right thoracic cage and its quantized histogram.

iii) Find the valley in the histogram whose area is the maximum. The area can be computed by

$$valley = \int_a^b (c - f(x)) dx \quad (4)$$

where c represents the highest point of the valley and $[a, b]$ represent the range of intensity of the valley. Then the threshold value, t , is set to equal to the intensity of the local minimum of the valley as shown in Fig.4.

iv) Convert an image of the right thoracic cage to a binary image using the threshold value obtained from step 3).

v) Detect the right boundary of the heart by using DBSCAN to remove noise from the boundary.

vi) Connect the right boundary of the heart by using the same non-linear least square approximation.

vii) Find the widest part on the right side of the heart by finding the maximum distance along the vertical line from the center of the body to the right boundary of the heart. The right boundary and its widest part, RCD, are shown in Fig. 4.

Fig 4: The right boundary of the heart and the widest part.

2.2.3 Thoracic Diameter Measurement

In this process, the diameter of the thoracic cage is computed by first finding the widest part of the thoracic cage and then measuring the distance from the left side to the right side of the thoracic cage. The boundary of the thoracic cage is detected by using the average intensity to convert an image to a binary image. Then the diameter is measured by calculating the distance from the left to the right boundary of the thoracic cage along each row. The maximum diameter, TD, is shown in Fig. 5(a). Then, the CTR can be calculated by

$$CTR = \frac{CD}{TD} \quad (5)$$

where $CD = LCD + RCD$ as shown in Fig. 5(b).

(a) The widest thoracic diameter. (b) The measurement of CTR.

Fig 5: The widest thoracic diameter and the measurement of CTR.

3. Experimental results

The proposed method is tested on a set of 255 chest radiographs which were taken in posterior-anterior position. All images are collected from King Chulalongkorn Memorial Hospital, Bangkok, Thailand. The format of the original images is DICOM format with a resolution of 2688x2208 pixels.

To validate efficiency of our work, a correlation test using Pearson's linear correlation coefficient is performed between two sets of numerical measurement results. The first set consists of RCD, LCD, CD, TD and CTR which were measured by our proposed technique and the second set which contains the same type of information but were measured by the radiologist. Some comparison results are displayed in Fig. 6 and the correlation results are demonstrated in Table 1. It is indicated in Fig. 6 that the numerical results between two datasets are quite similar.

Table 1: Correlation test results

(b) The points to measure CTR selected by the proposed method.

Fig 6: the comparison results

4. Conclusion

This paper presents a new method to automatically measure the CTR from an input image of a Posterior-Anterior chest radiograph by using non-linear least

square approximation and local minimum. In Table 1, the results of CTR measurement show quite a promising trend between two numerical datasets. However, these results can be improved because some of the chest radiographs might contained pericardial fat pad or vascular shadow whose intensities are similar to the heart which cause the measurement of RCD and LCD to be discrepancy.
