RPCRUTMA2=	Relative Price Change of Rubber Export of Thailand Compare to Malaysia During 1991-1995
SUPRTUS1	= Supply Availability of Thai Rice Export Compare to USA During 1986-1990
SUPRTUS2	= Supply Availability of Thai Rice Export Compare to USA During 1991-1995
SUPRTV1	= Supply Availability of Thai Rice Export Compare to Vietnam During 1986-1990
SUPRTV2	= Supply Availability of Thai Rice Export Compare to Vietnam During 1991-1995
SUPRUTIN1	= Supply Availability of Thai Rubber Export Compare to Indonesia During 1986-1990
SUPRUTIN2	= Supply Availability of Thai Rubber Export Compare to Indonesia During 1986-1990

Rubber Smoked Sheet (RSS) Production

Unsmoked Sheets Rubber (USS) is initially produced by smallholder. After delivery of USS to a factory the sheet rubber has to undergo the processing steps such as cleaning, smoking, grading and packing before it is shopped out to consumers. The rubber to be sold in the international markets has to conform to the International Standards of Quality and Packing for Natural Rubber Grades (The Green Book) over which the Rubber Control Act of the Department of Agriculture enforces control.

Technically Specified Rubber (TSR) or (TTR) (Thai Tested Rubber)

TSR (Block Rubber) can be produced into different grades from different types of raw material: fresh latex, field coagulum, USS , RSS , and Scrap rubber.

The processing consists of three stages: breaking of rubber into small side called communitied rubber, continuous drying in a tunnel with hot air, and weighting, processing and packing into pallet.

All the stages of processing are under constant controls with modern machinery and rubber technology to maintain its quality under the technical specifications.

Air Dried Sheet (ADS) Production

Air dried sheet rubber is the sheet rubber which has the same production process as RSS but is under strict control and dried with hot air without smoke. Bleaching agents are not normally used in the process.

Latex Concentrate

Latex concentrate has a dry rubber content of 60% and has been found to be uniform in its standard quality and suitable for many important latex processes into manufactured products

APPENDIX C:
Regression Results of Competitiveness Residual

Standard Regression Output

Regression Coefficients

Each coefficient multiplies the corresponding variable in forming the best prediction of the dependent variable. The coefficient measures the contribution of its independent variable to the prediction. The coefficient of the series called C is the constant or intercept in the regression--it is the base level of the prediction when all of the other independent variables are zero. The other coefficients are interpreted as the slope of the relation between the corresponding independent variable and the dependent variable.

Standard Errors

These measure the statistical reliability of the regression coefficients--the larger the standard error, the more statistical noise infects the coefficient. According to regression theory, there are about 2 chances in 3 that the true regression coefficient lies within one standard error of the reported coefficient, and 95 chances out of 100 that it lies within two standard errors.

t-Statistic

This is a test statistic for the hypothesis that a coefficient has a particular value. The t-statistic to test if a coefficient is zero (that is, if the variable does not

belong in the regression) is the ratio of the coefficient to its standard error. If the t-statistic exceeds one in magnitude it is at least two-thirds likely that the true value of the coefficient is not zero, and if the t-statistic exceeds two in magnitude it is at least 95 percent likely that the coefficient is not zero.

Probability

The last column shows the probability of drawing a t-statistic of the magnitude of the one just to the left from a t distribution. With this information, you can tell at a glance if you reject or accept the hypothesis that the true coefficient is zero. Normally, a probability lower than .05 is taken as strong evidence of rejection of that hypothesis.

R²

This measures the success of the regression in predicting the values of the dependent variable within the sample. R^2 is one if the regression fits perfectly, and zero if it fits no better than the simple mean of the dependent variable. R^2 is the fraction of the variance of the dependent variable explained by the independent variables. It can be negative if the regression does not have an intercept or constant, or if two-stage least squares is used.

R² adjusted for degrees of freedom

This is a close relative of R² in which slightly different measures of the variances are used. It is less than R² (provided there is more than one independent variable) and can be negative.

Standard Error of the Regression

This is a summary measure of the size of the prediction errors. It has the same units as the dependent variable. About two-thirds of all the errors have magnitudes of less than one standard error. The standard error of the regression is a measure of the magnitude of the residuals. About two-thirds of the residuals will lie in a range from minus one standard error to plus one standard error, and 95 percent of the residuals will lie in a range from minus two to plus two standard errors.

Sum of Squared Residuals

This is just what it says. You may want to use this number as an input to certain types of tests.

Log Likelihood

This is the value of the log likelihood function evaluated at the estimated values of the coefficients. Likelihood ratio tests may be conducted by looking at the difference between the log likelihoods of restricted and unrestricted versions of an equation.

Durbin-Watson Statistic

This is a test statistic for serial correlation. If it is less than 2, there is evidence of positive serial correlation.

Akaike Information Criterion

The Akaike Information Criterion, or AIC, is a guide to the selection of the number of terms in an equation. It is based on the sum of squared residuals but places a penalty on extra coefficients. Under certain conditions, you can choose the length of a lag distribution, for example, by choosing the specification with the lowest value of the AIC.

Schwarz Criterion

The Schwarz criterion is an alternative to the AIC with basically the same interpretation but a larger penalty for extra coefficients.

F-Statistic

This is a test of the hypothesis that all of the coefficients in a regression are zero (except the intercept or constant). If the F-statistic exceeds a critical level, at least one of the coefficients is probably non-zero. For example, if there are three independent variables and 100 observations, an F-statistic above 2.7 indicates that the probability is at least 95 percent that one or more of the three coefficients is non-zero. The probability given just below the F-statistic enables you to carry out this test at a glance.
