KEYWORD: Solid oxide electrolysis cells, Nickel alloy electrode, Hydrogen production, Steam electrolysis, Oxidation tolerance

Aritat Wongmaek : DEVELOPMENT OF NICKEL ALLOY HYDROGEN ELECTRODES FOR SOLID OXIDE ELECTROLYSIS CELL. Advisor: Asst. Prof. Pattaraporn Kim, Ph.D.

The conventional nickel-yttrium stabilized zirconia (Ni-YSZ) cathode in solid oxide electrolysis cell (SOEC) suffers from oxidation after exposed to steam during electrolysis for hydrogen production. The Ni-chromium (Cr)-iron (Fe) alloys with various compositions are introduced to improve cathode oxidation resistance. This study aims to study the effect of alloy contents and determine suitable fabrication method for SOEC cathode. The alloy containing cathode should satisfy both high electrochemical performance and low degradation rate. The content of Fe and Cr are varied in the range of 0-20%wt when the weight ratio of metal to YSZ is maintained constantly at 60:40. The SOEC having Ni-Cr-Fe alloy cathode are fabricated. The oxidation resistances are studied using thermogravimetric analysis (TGA). The electrochemical performance is carried out using current/potential characteristic curve and electrochemical impedance spectroscopy (EIS). The operating temperature is controlled between 650-900 °C with the feed containing steam to hydrogen ratio of 70:30. Electrolyte-supported 55Ni5Cr-YSZ/YSZ/Pt shows the highest current density of  $-1.09 \text{ A/cm}^2$  at 1.8 V, 800 °C, compared to the other NiCr alloy compositions. For NiFe cathode in the electrolyte-supported cell, the sample cracked due to the thermal expansion after sintering at 1,100 °C for 2 hr. The sintered cathode supporting layer of various alloys loading were fragile and brittle. The wash-coating and impregnating technique was introduced as an alternative method to fabricate the alloy containing cathode. The Ni alloys impregnated improved the durability of SOEC while lowering the performance. The highest current density of conventional Ni-YSZ/ YSZ/ BSCF and alloy-impregnated Ni-YSZ/ YSZ/ BSCF was  $-0.50$  and  $-0.26 \text{ A/cm}^2$ , respectively. For wash-coated electrode, the dense grains were formed which was not suitable for the hydrogen electrode due to lacking of three phase boundary.

Field of Study: Chemical Engineering

## ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to my advisor Asst. Prof. Pattaporn Kim for her patience, motivation and her kindness advice. Her guidance and support helped me a lot in the research and thesis writing. Also, the SOEC project student for giving their consulting in life and projects and happiness sharing.

Secondly, this research was financially by the PTT public company limited. I would like to express my special thanks to All of the PTT hydrogen project's staffs for providing me an opportunity and the valuable guidance. My sincerely thanks are also to lecturers, scientists, officers and friends in faculty of chemical engineering, Chulalongkorn university.

Last but not the least I would like to express my sincerely acknowledge to my family for their support, inspiration and encouragement in everyday life.

Aritat Wongmaek

# Chapter I

## Introduction

### 1.1. Motivation

Thailand energy sources are mainly depending on the petroleum resources [1]. They are imported in form of processed and crude oil. The prices are unstable, and uncontrollable. These affects to the energy security of Thailand. The definitions of energy security are adequate, affordable and reliable supplied [2]. The technology of energy production with low price and environmental sustainability is the key priorities to increase Thailand energy security. The requirement for clean and sustainable fuel sources has encouraged great interests in electrochemical technologies such as high temperature solid oxide electrolysis cell (SOEC). Hydrogen produced from renewable electricity through SOEC is promising as a next generation fuel. The operating temperature of SOEC was in the range of 700 – 1000 °C. The advantage of using high temperature electrolysis is the improvement of electrochemical reaction rates and reduction of electrical energy demand. It can also provide an efficient hydrogen production [3-5]. However, high operating temperature also accelerates oxidation of electrode under high steam environment [6, 7]. Yttria-stabilized zirconia (YSZ) has been widely used as an electrolyte material because it shows a good thermal and chemical stability and performs as a good oxide-ion conductor with enough mechanical strength [8]. Nickel-yttria stabilized zirconia (Ni-YSZ) is therefore generally used as hydrogen electrode in SOEC because of its good thermal compatibility with the electrolyte [9] and good catalytic properties [10-12].; nevertheless, the material shows low durability due to Ni oxidation under high steam partial pressure, resulting in lowered electronic conductivity and catalytic activity of the electrode. The Ni-Cr-Fe

alloys are introduced to improve the hydrogen electrode oxidation resistance. These alloys are generally used as an electrode for hydrocarbon cracking reaction and coke prevention [13-15], an interconnect [16-18] and the supported metal [19-21] of solid oxide fuel cell (SOFC). The alloy supports have a good thermal conductivity and ductility which may develops the thermal shock resistance, cell temperature gradient [22] and also improved the mechanical strength of the electrode. The oxidation resistance was reported to enhance with the increasing of alloys contents [7, 23]. Two most critical properties of SOEC's hydrogen electrode are a similar thermal expansion matching with electrolyte and high oxidation resistance in the operating environment of the SOEC. To achieve both characteristics, the suitable alloy composition was considered.

In this study, the effects of chromium and iron additions to a Ni-alloy based hydrogen electrode was investigated. Thermal expansion behavior, oxidation rate, and electrochemical performance was measured. The electrode application in SOEC was also investigated.

## 1.2. Research objective

To study the effect of Ni-alloy on the performance of hydrogen electrode in solid oxide electrolysis cell

Subobjective includes:

1.2.1 To study the effect of alloy contents on the hydrogen electrode fabrication.

1.2.2 Improve the oxidation resistance and electrochemical performance of hydrogen electrode in operating environment comparing to conventional electrode.

1.2.3 To investigate the electrochemical performance and stability of conventional and Ni alloy based SOEC

### 1.3. Research scope

1.3.1 Varying the content of Fe and Cr in the range of 0-20 wt% when the weight ratio of metal to YSZ is maintained constantly at 60:40.

1.3.2 Comparing the effects of alloy deposition method between wash-coating and conventional dry-pressing on electrochemical performance test using current/potential characteristic curve and electrochemical impedance spectroscopy (EIS)

1.3.3 Comparing the durability between alloys wash-coated Ni-YSZ/YSZ/BSCF and conventional Ni-YSZ/YSZ/BSCF at constant potential at 1.1V.

### 1.4. Expected benefit

1.4.1 Electrode material which has a higher electrochemical performance and higher oxidation resistance

1.4.2 Research project to Fabricate a SOEC to decrease the emission of carbon to the environment with renewable energy source toward Thailand Low-Carbon Societies.

1.4.3 Development of Thailand energy security with reducing hydrogen synthesized from hydrocarbon.

## Chapter II

### Literature review

#### 2.1. Solid oxide electrolysis cell (SOEC)

Solid oxide electrolysis cell is a device to produce hydrogen and oxygen by applying electricity to water. This is the reverse of the process that occurs in a fuel cell. The cell consists of three parts, hydrogen electrode, oxygen electrode and electrolyte. The schematic drawing of SOEC is shown in Fig.1. Steam is fed into the porous cathode. Steam reacts with the electron to form hydrogen gas and oxygen ion. Oxygen ion pass through electrolyte membrane and reacts at anode to form oxygen gas and generate electron as shown in equation (1)-(3).

Hydrogen electrode reaction

Oxygen electrode reaction

Overall reaction

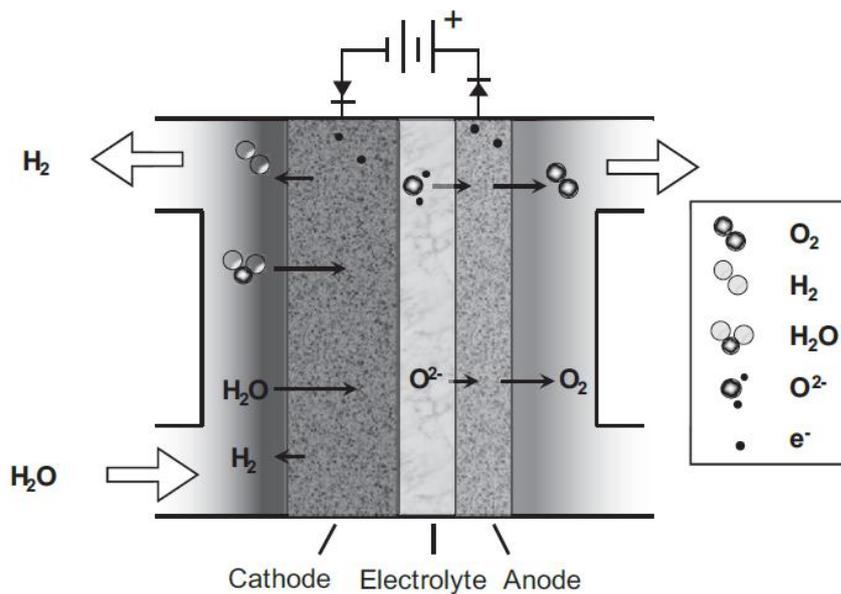

Fig. 1 The schematic drawing of SOEC principle[9]

The reaction takes place at the triple phase boundary (TPB). Three phases are ion conductor (electrolyte), electron conductor (metal) and pore phase for transporting gas and steam. TPBs are electrochemical active site. Increasing TPB density will increase the reaction rate and increase the electrochemical performance. The schematic diagram of TPB can be seen on Fig. 2

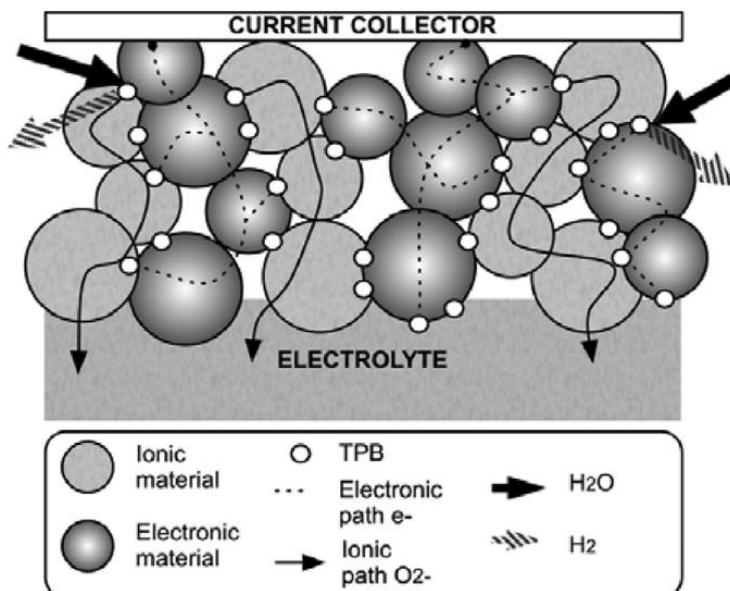

Fig. 2 The schematic drawing of the triple phase boundary in hydrogen electrode-electrolyte [9]

The low temperature electrolysis such as proton exchange membrane (PEM) [24-27] are generally used with low operating temperature (<100°C). The disadvantage is high demand of electrical energy due to thermodynamics. The total energy demand ( $\Delta H$ ) for SOEC can be showed by equation (4)

$$\Delta H = \Delta G + T\Delta S \quad (4)$$

Where  $\Delta G$  is the required electrical energy (Gibbs free energy),  $T\Delta S$  is the demand of thermal energy for the process (J/mol  $H_2$ ). From Fig. 3, when increasing operating temperature, the demand of electrical energy decreases. Therefore, high operating temperature electrolysis provides opportunities to use the waste thermal energy from industry to produce hydrogen. Waste thermal energy from output gasses can also be recovered as shown in Fig. 4. The comparison of electrolysis technologies is demonstrated in table 1.

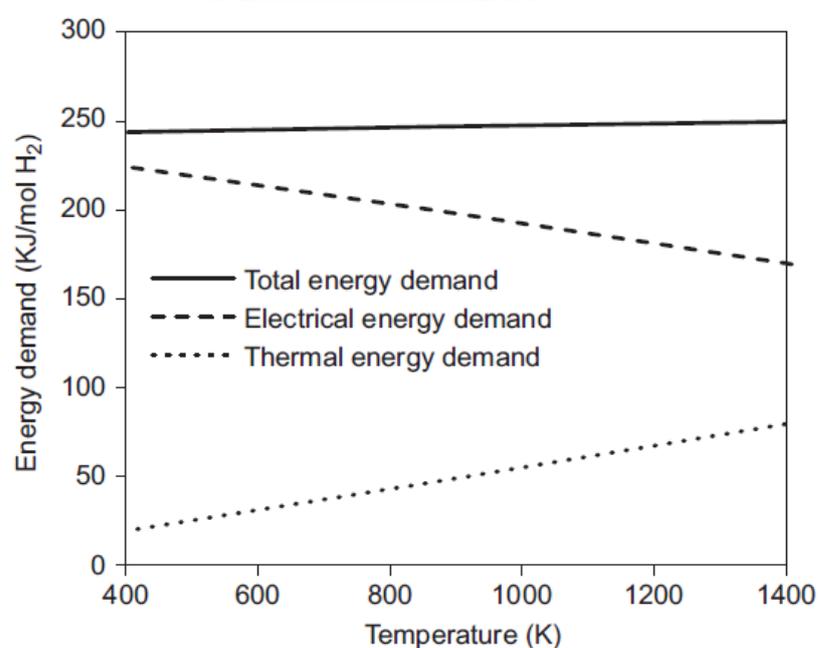

Fig. 3 The calculation of required energy for  $H_2$  production from steam electrolysis [8]

## 2.2. Hydrogen electrode (cathode)

Hydrogen electrode is used to support steam and hydrogen diffusion. Noble metals, such as Platinum (Pt) and non-valuable metal such as Nickel (Ni) can be selected as SOEC cathode. Because of high cost of noble metal, formation of volatile oxides and aging of porous structure at a high temperature, the used of Pt is not suitable [28]. To develop the TPB active site, Ni is mixed with ion conductor Yttria stabilized zirconia (YSZ). Electrochemical performance of Ni-YSZ electrode is studied by many researches. Eguchi et al. [29] studies the characteristic of IV polarization of Ni-YSZ and Pt hydrogen electrode. It is found that Ni-YSZ performs better in the Solid Oxide Fuel Cell (SOFC) mode but suffers from higher potential used in the SOEC mode. It is assumed that the Ni is oxidized to form NiO which has lower active site, resulting in low performance. The long-term performance is interested in many literatures. Maskalick [30] studies and tests the electrochemical performance stability of SOEC. The test is maintained for 450 hr at 1,000 °C. The performances at operating time between 0 – 500 h are shown on Table 2. The electrical resistance of the cell is constant at 5.5 m $\Omega$ .

*Table 2 Electrolysis cell performance, at 1,000 °C [30]*

### 2.3. Hydrogen electrode degradation

High temperature SOEC has many advantages compared to low temperature electrolysis. Both ohmic conductivity and reaction kinetics are developed by elevating temperature, which reduces the internal resistance in cell and increase the efficiency. However, the initial performance is not the only requirement, but also long-term stability in operating conditions. Hydrogen electrode degradation is considered as a key limitation that lower the performance of the SOEC. To increase the durability and extend the electrode lifetime, the cathode is required to develop the microstructure by changing or replacing the electrode with alternative materials.

Haunch et al. [31] investigates on microstructure of hydrogen electrode and reports that for long-term stability for SOEC at high current density and high humidity condition, the NiO-YSZ precursor should be 1) as dense with fine particle and pore size as possible, 2) the three phases should be size-matched and homogeneously dispersed. The cell specifications are shown on the table 3. Cell C with fine microstructure with dense structure provides the highest durability for both polarization and ohmic resistance over time compared to others (Fig. 5).

*Table 3 Cell and test conditions for Cell A, B, C and D [31].*

| Name   | Cell specifications   | Qualitative microstructure information   | Test specifications   |
|--------|---|--|---|
| Cell A | No specific fuel electrode layer. Support layer functioning as fuel electrode (Ni/3YSZ) | Coarse structure. Significantly higher pore fraction than Cell B, C and D      | 800 °C, p(H <sub>2</sub> O)/p(H <sub>2</sub> ):90/10, 56% H <sub>2</sub> O conversion, -1 A/cm <sup>2</sup> , 1000 h    |
| Cell B | Support layer (Ni/3YSZ) and active fuel electrode layer (Ni/8YSZ)                       | Coarse microstructure. As dense as possible for a Ni/YSZ:40/60 fuel electrode. | 800 °C, p(H <sub>2</sub> O)/p(H <sub>2</sub> ):90/10, 56% H <sub>2</sub> O conversion, -1 A/cm <sup>2</sup> , 1000 h    |
| Cell C | Support layer (Ni/3YSZ) and active fuel electrode layer (Ni/8YSZ)                       | Fine microstructure. As dense as possible for a Ni/YSZ:40/60 fuel electrode.   | 800 °C, p(H <sub>2</sub> O)/p(H <sub>2</sub> ):90/10, 56% H <sub>2</sub> O conversion, -1 A/cm <sup>2</sup> , 2000 h    |
| Cell D | Sister-cell to cell C   | Fine microstructure. As dense as possible for a Ni/YSZ:40/60 fuel electrode.   | 800 °C, p(H <sub>2</sub> O)/p(H <sub>2</sub> ):90/10, 56% H <sub>2</sub> O conversion, -1.25 A/cm <sup>2</sup> , 1000 h |

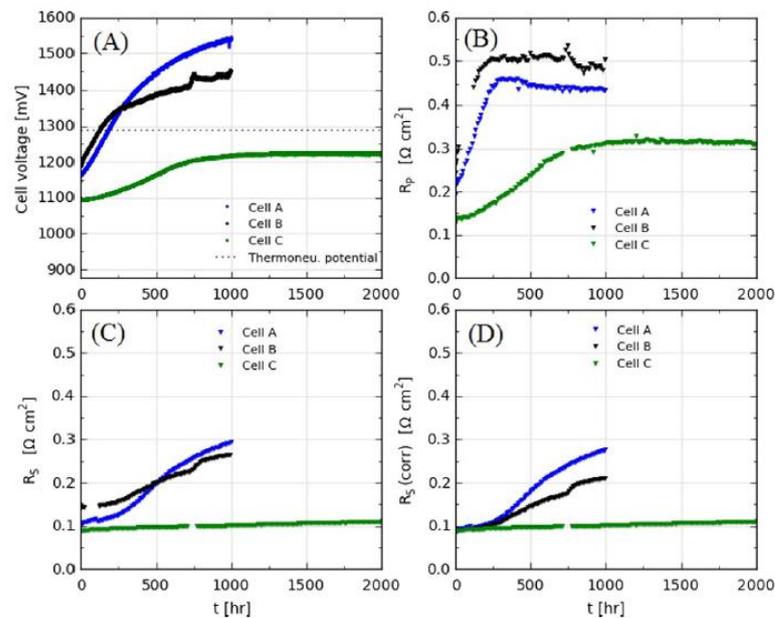

Fig. 5 Long term electrolysis testing of Cell A, B and C at  $1\text{A}/\text{cm}^2$ ,  $800^\circ\text{C}$ . A) Cell potentials, B) total polarization resistances ( $R_p$ ), C) ohmic resistances ( $R_s$ ) and D) ohmic resistances ( $R_s$ ) over time at the same beginning [31].

Ni particle agglomeration in the hydrogen electrode decreases the density of active TPB sites. It affects in both SOFC and SOEC. Hauch et al. [32] also reports that the initial rate of agglomeration is caused by the increasing of H<sub>2</sub>O partial pressure. The role of initial microstructure of Ni-YSZ cathode is also important. The initial performance decreases with the increasing of initial particle size because of Ni agglomeration increased [6]. The schematic drawing of Ni agglomeration was shown in Fig.6.

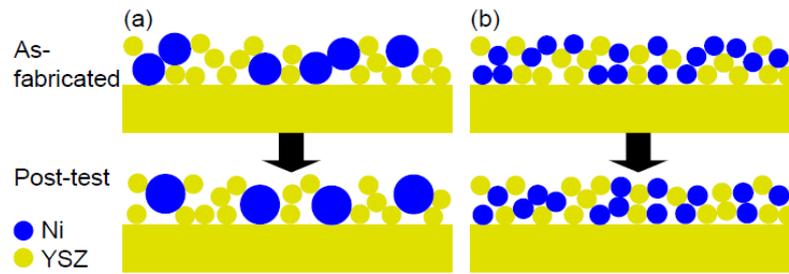

Fig. 6 Schematic drawing of Ni agglomeration in Ni-YSZ electrodes at 840 °C; Ni (blue), YSZ (yellow); a) Large Ni particles are easier to agglomerate, which reduce the interface connectivity and TPB active sites; b) Small Ni particles are harder to agglomerate over time [6].

Other several phenomena that affect the stability of Ni-YSZ cermet have been observed. The evaporation and re-precipitation due to variable oxygen activities within the cathode layer are investigated. At equilibrium with a humid gas, the thermodynamic data from Fig. 7 indicates that  $\text{Ni(OH)}_2(\text{g})$  is the most volatile species in a gas mixture of  $\text{H}_2\text{O}$  and  $\text{H}_2$ . Its partial pressure is six order higher than the pure  $\text{Ni}(\text{g})$ . The partial pressure of Ni significantly increases due to the addition of small quantities of water vapor. The deposition process can be described by equation 5 and 6. The illustration of vaporization-deposition process is shown on Fig. 8.

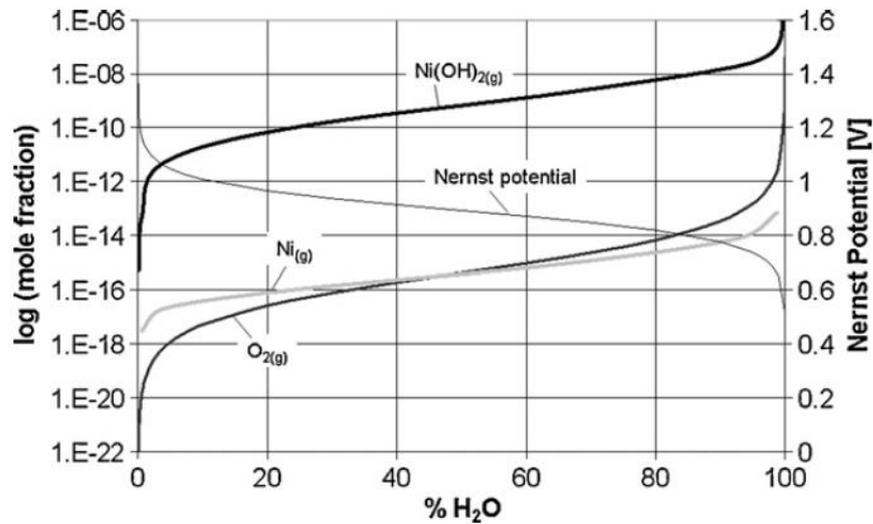

Fig. 7 Thermodynamic data for  $\text{Ni(g)}$  and  $\text{Ni(OH)}_2\text{(g)}$  in the gas mixture of hydrogen gas and steam at 950 °C [33].

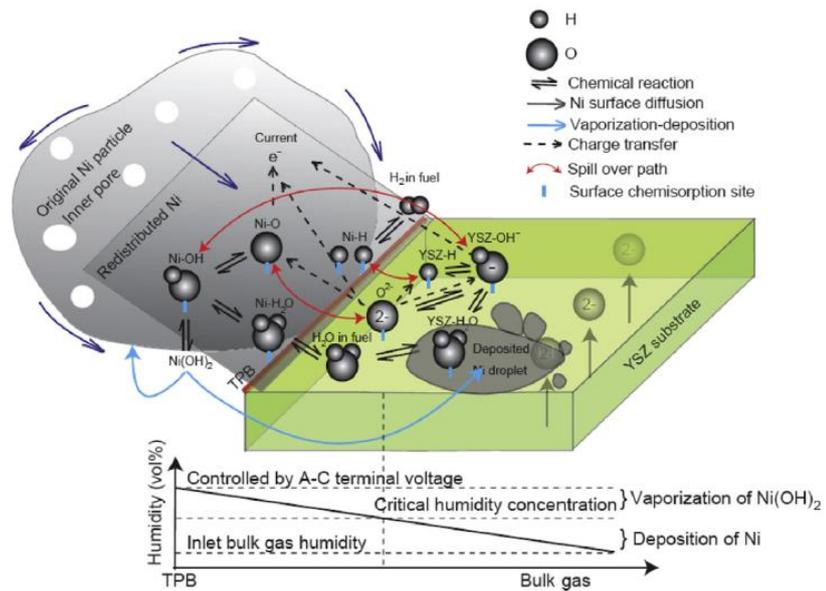

Fig. 8 Schematic drawing of local Ni alignment and vaporization–deposition processes at TPB [34].

The conventional Ni-YSZ electrode suffers from a reduction-oxidation cycle. The structural instabilities occur during re-oxidation, it leads to serious degradation in

SOEC performance. The oxidation tolerance of Ni-YSZ is studied at several temperatures by Laurencin et al. [35]. Fig. 9 shows the result of Ni-YSZ tolerance under 20% O<sub>2</sub> between 600 to 800 °C. The oxidation rate boosts when the temperature increases. At 800 °C, the oxidation of the cermet is fully oxidized in a few minutes. The degree of oxidation (DoO) is expressed by equation 7

$$\text{DoO} (t) = \frac{m(t) - m_{\text{Ni-YSZ}}}{m_{\text{NiO-YSZ}} - m_{\text{Ni-YSZ}}} \quad (7)$$

Where  $m_{\text{Ni-YSZ}}$  is the initial mass of the reduced sample,  $m(t)$  is the mass at time  $t$  during oxidation and  $m_{\text{NiO-YSZ}}$  is the fully oxidized mass of sample.

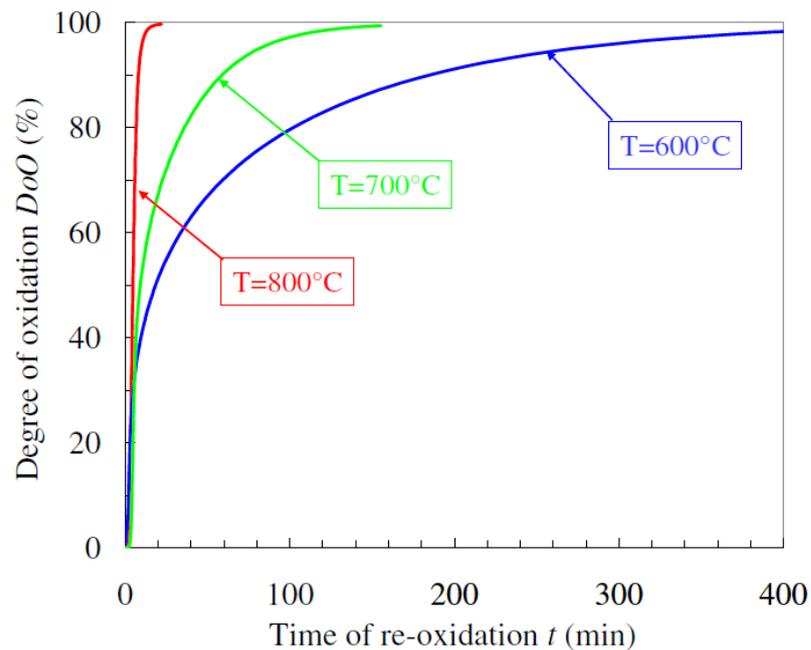

Fig. 9 DoO of a Ni-YSZ cermet at 600 - 800 °C, under 20% O<sub>2</sub> in helium (and a total flow rate 5 Lh<sup>-1</sup>) [35].

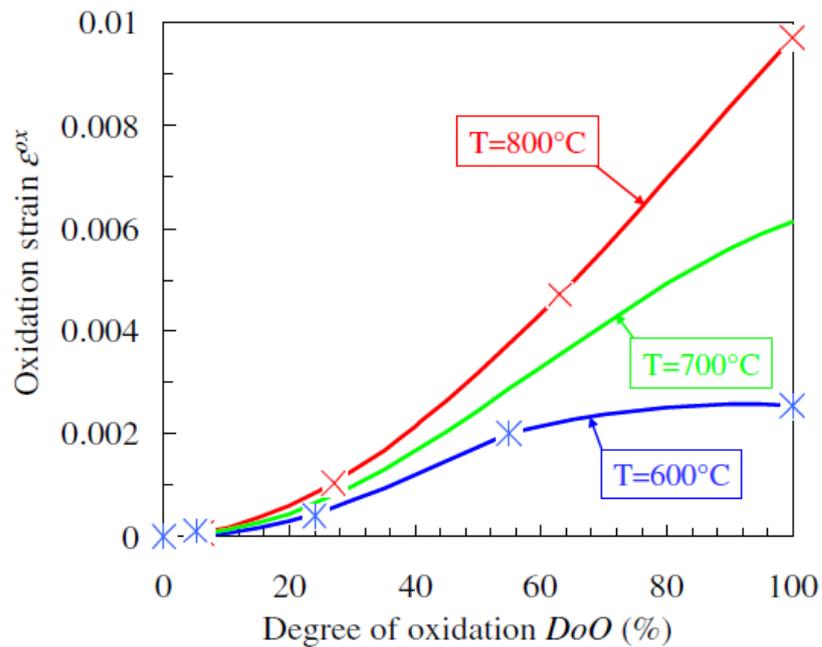

Fig. 10 Effect of the oxidation degree on the structural expansion of the studied cermet upon oxidation in 0.3 and 20%  $O_2$  at 600 and 800 °C. [35].

Fig. 10 shows the plot between oxidation strain and degree of oxidation. At low oxidation degree ( $DoO < 5\%$ ). Dimensional expansion is not detected. At high oxidation degree ( $DoO > 5\%$ ), the cermet expansion is boosted with the increasing oxidation temperature. When the 1 mm thick cermet was fully oxidized, the expansion strain was reported at 0.97% at 800 °C.

To enhance the performance of hydrogen evolution reaction (HER) of the hydrogen electrode, the doped metal such as manganese (Mn), neodymium (Nd), iron (Fe) and chromium (Cr) is suggested. It improves the adsorption due to the higher catalytic active sites [36]. Zhang J. et al. [37] develops N-doped bamboo-like carbon nanotube consisted of Fe-Ni-Cr as an electrocatalysts for water-splitting. The HER electrochemical performance is shown in Fig. 11. Fe-Ni-Cr/NC shows lowest over-

potential (exclude Pt/C) to drive  $10 \text{ mA/cm}^2$  which indicates the best catalytic performance for HER.

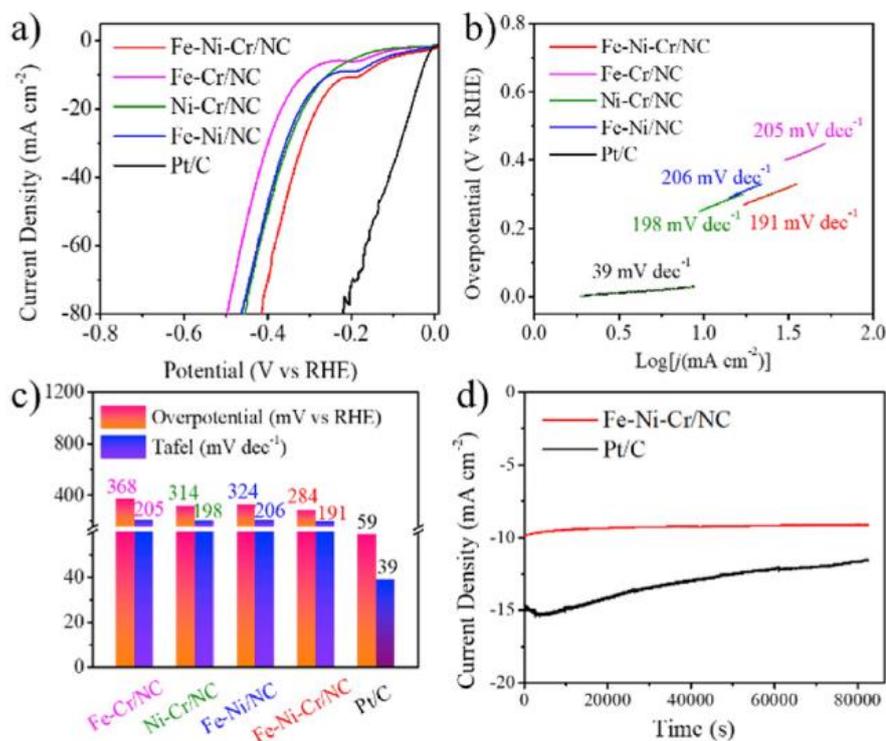

Fig. 11 LSVs of Fe-Ni-Cr/NC, Fe-Cr/NC, Ni-Cr/NC, Ni-Fe/C and Pt/C with a scanning rate of  $5 \text{ mVs}^{-1}$  in 1M KOH (a) and corresponding Tafel slopes (b), (b) Bar plots of overpotentials (@ $10 \text{ mA cm}^{-2}$ ) and Tafel slope, (d) Long-term stability measurement of Fe-Ni-Cr/NC and Pt/C in 1 M KOH via chronoamperometry measurement. [37]

## 2.4. Ni-Cr-Fe alloys

To develop the oxidation tolerance of hydrogen electrode, The Ni-Cr-Fe alloys are introduced. Ni-Fe alloys are known as the primary material for the hydrogen electrode support due to their oxidation resistance. The effects of Fe loading in Ni based support are studied by Wang X. et al. [38]. The  $\text{Fe}_2\text{O}_3$  loading are varied from 0 -50 % wt. the oxidation behavior is shown in Fig. 12a and 12b at 600 and 750 °C

respectively. The addition of Fe loading improves the oxidation tolerance in both operating temperatures. They also investigated the thermal expansion which is considered as a key parameter for cell fabrication. Coefficient of thermal expansion (CTE) of 0 – 50 % wt. Fe are 16.1 15.9 14.5 and 12.1  $\times 10^{-6} \text{K}^{-1}$  respectively, as seen in Fig. 12c.

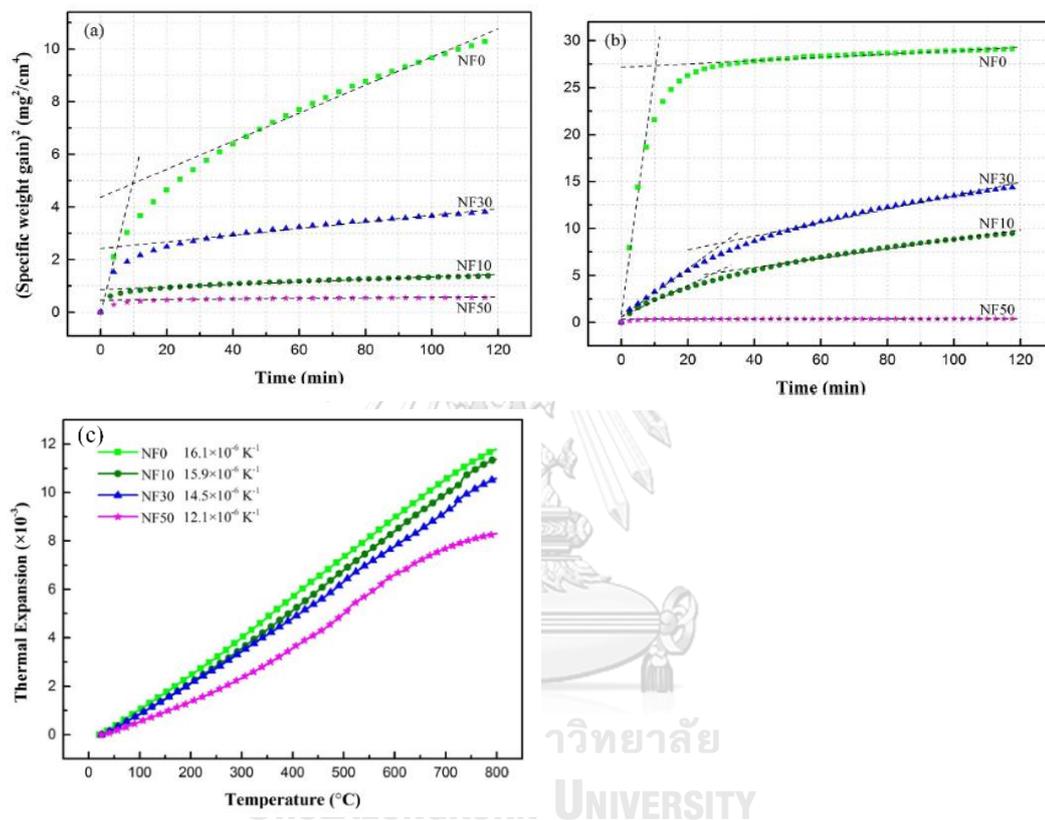

Fig. 12 specific weight gain of the porous Ni-Fe alloys anode supports oxidized in air at (a) 600 °C ,(b) 750 °C and (c) Thermal expansion of Ni-Fe alloy anode supports in Ar as a function of temperature [38]

The important of Ni based alloys on corrosion and oxidation at superheated steam is investigated by Hamdani [39]. Fig. 13 shows the oxidation behavior of Ni-Cr-Fe alloys which exposed to the 700 °C steam for 500 hr. The effect of Cr content is

varied. Both mirror and electro-polished samples show a higher oxidation rate. The addition of Fe content reduces the oxidation resistance of Ni-Cr based alloys.

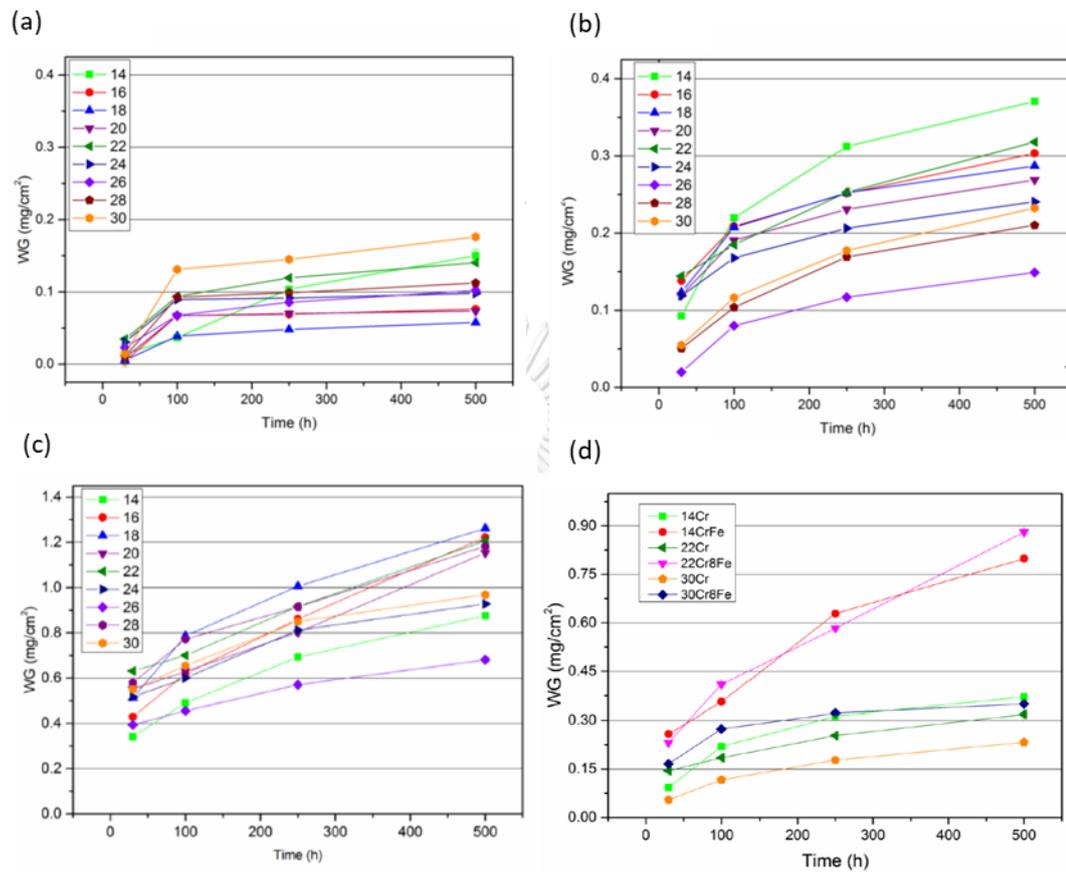

Fig. 13 weight gain measurement for NiCr model alloys exposed to superheated steam at 700 °C for 500 hr: (a) emery-polished (#2400), (b) mirror polished (c) electro-polished and (d) mirror polished of Ni-Cr-Fe [39]

CTE of pure Nickel at various temperature is studied by Hwang J.W. [40] and the results shows in Table 4 and Fig. 14. It presents that the highest expansion occurs at 330 °C.

Table 4 Thermal expansion coefficients of pure nickel at various temperature [40]

| Temperature<br>(°C) | Thermal expansion<br>coefficient ( $\times 10^6$ ) °C <sup>-1</sup> |
|---------------------|---|
| 100                 | 15.3  |
| 270                 | 17.6  |
| 320                 | 21.1  |

| 1000                | 22.1  |

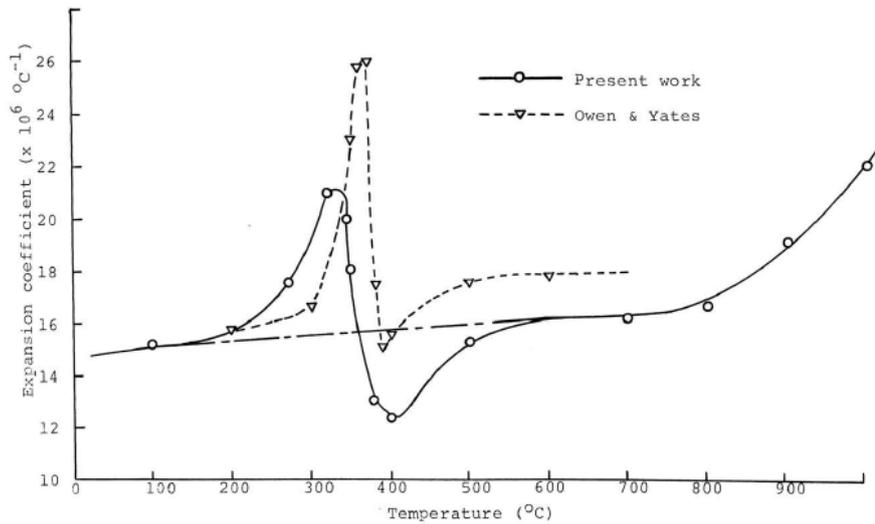

Fig. 14 CTE versus temperature of nickel [40]

Then the expansion of pure iron is reported in Fig. 15. It increases with the increasing of temperature. The CTE rapidly correlates to the anomalous change of

lattice parameter. This clearly represents that the thermal expansion of pure iron is affected by the magnetostriction. The expansion of iron increases and becomes constant and falling at the Curie temperature. The Curie temperature is a temperature which magnetic materials sharp transform their magnetic properties. At Curie point, ferromagnetic turns to paramagnetic.

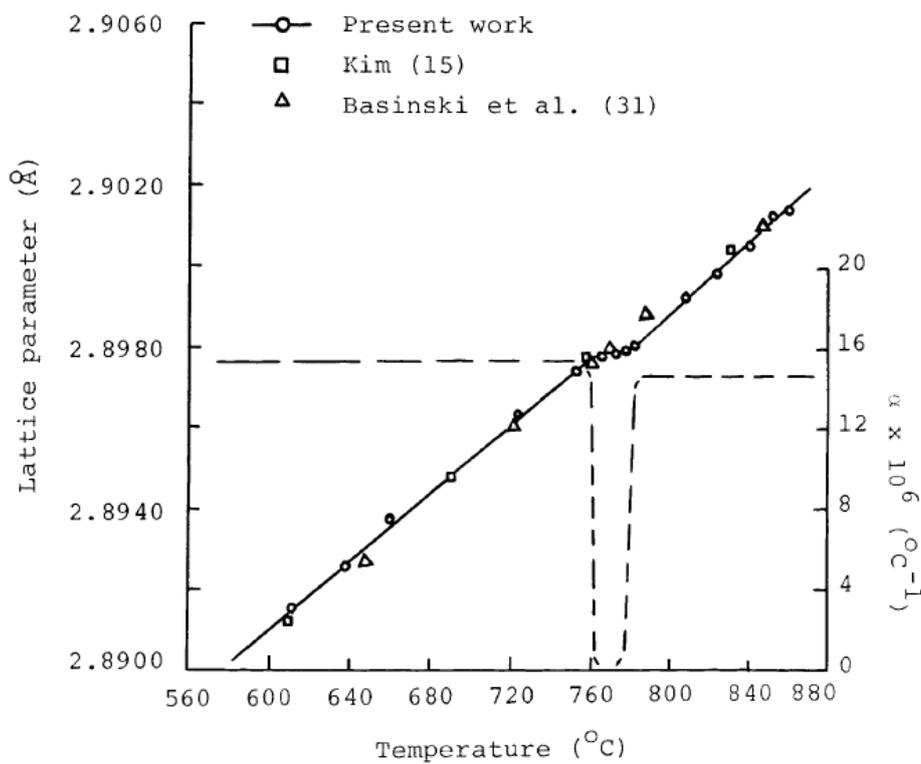

Fig. 15 Lattice parameter and  $\alpha$  of sample B, 99.985% Fe at the Curie temperature. Expansion coefficient  $\alpha$  – to the right. [40]

Hidnert [41] studied the thermal expansion behavior of Ni-Cr alloys. The average coefficients of expansion are shown in Table 5. The anomalous change is not detected.

Table 5 Average coefficients of expansion of hot-rolled nickel-chromium alloys [41]

| Sample | Chemical composition |      | Average coefficients of expansion per degree centigrade |                  |                  |                  |                  |                  |                  |                  |                  |                  |                  |

Church et al. [7] studies both coefficient of thermal expansion (CTE,  $\alpha_T$ ) and oxidation resistance of varying alloy contents. Fig 16 shows the effect of Cr contents (Fe:Ni = 1) on CTE. Increasing Cr contents, decreases the Curie temperature and increase the CTE at above Curie point. The thermal expansion behavior below Curie temperature is the result from strong spontaneous magnetostriction in the magnetic state [42, 43]. For Fig. 17, the constant Cr with increasing Ni content affect both Curie temperature and also the average of CTE values (before and after the Curie Temperature). With increasing Ni content, CTE decreases at pre-Curie and increases at post-Curie. The Curie temperature and average CTE are shown on table 6.

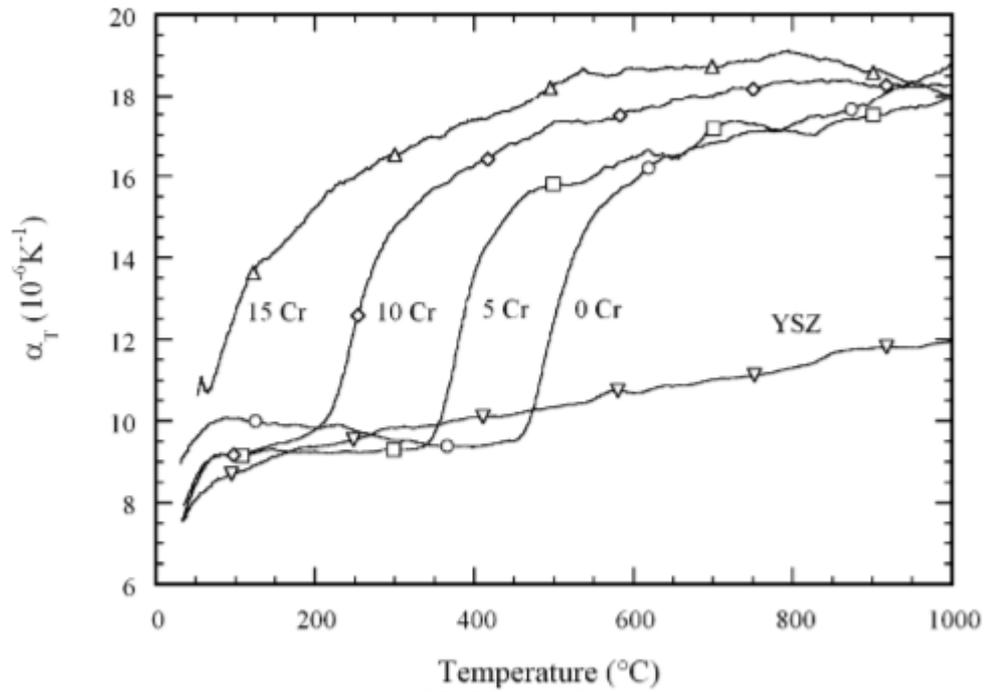

Fig. 16 CTE of Fe-Ni-Cr (Fe:Ni=1) alloys and 8 mol% YSZ. [7].

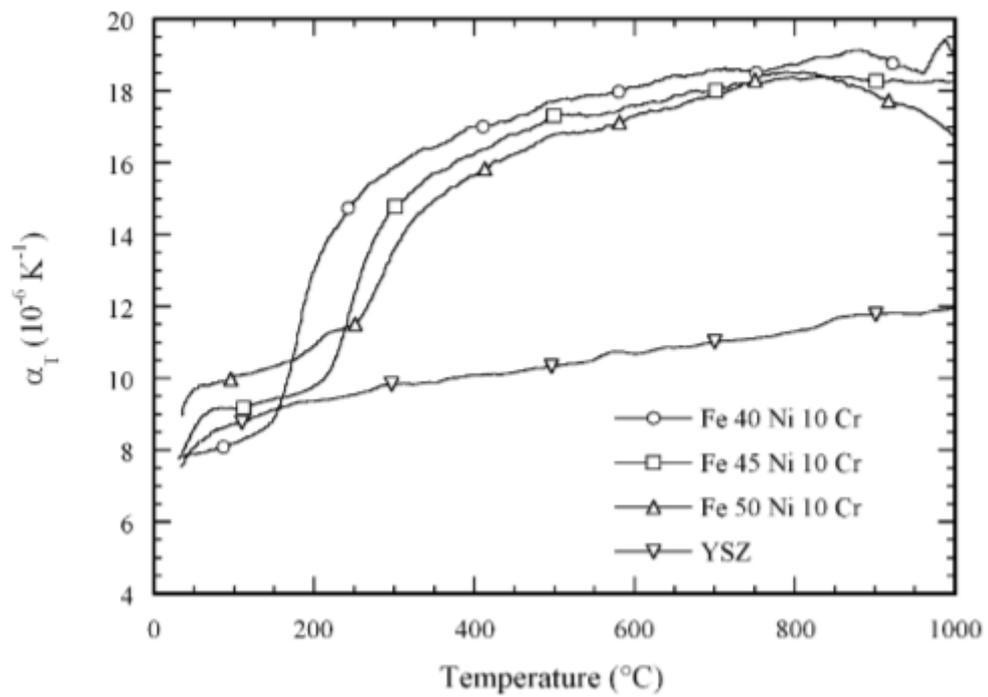

Fig. 17 CTE of Fe-Ni-Cr alloys with constant %wt Cr and 8 mol% YSZ. [7].

Low and high temperature CTE were calculated in the range of 20 °C to ( $T_c - 50$ ) and from ( $T_c + 50$ ) to 1000 °C, respectively.

<sup>a</sup>  $\alpha_M$  calculated from 20 to 500 °C (low) and 500 to 1000 °C (high).

<sup>b</sup> Curie temperature was not measurable.

<sup>c</sup> CTE was not reported due to the  $\alpha$ - $\gamma$  phase transition in this temperature range.

Thermal expansion mismatch is one of the important properties that affects the stability of electrode at operating environment. The results of Cr addition are shown on Fig. 18. The Fe50Ni and Fe47.5 have similar CTE with YSZ up to 450 °C.

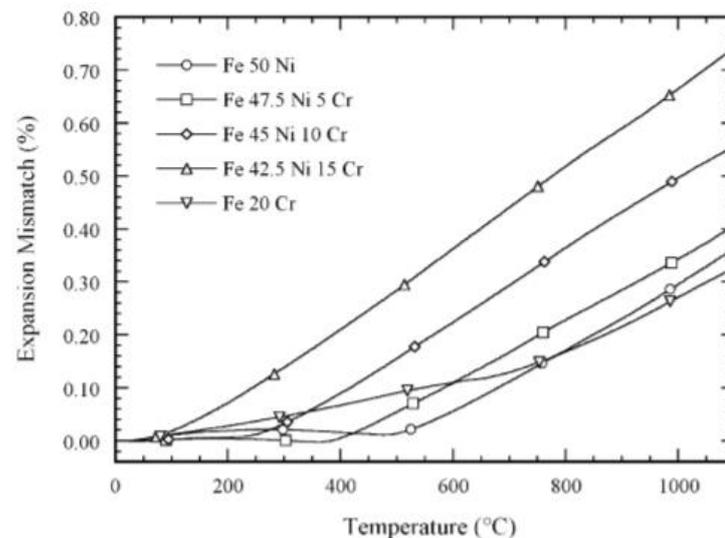

Fig. 18 Expansion mismatch with YSZ at room temperature to 1000 °C [7].

Ni based alloys has a capacity to form a protective oxide layer which mainly involves of chromium. The Ni based alloys at various compositions is investigated by Hamdani [39]. The outer layer is affected by the steam corrosion as seen in Fig. 19. The existing nodules trends to decrease with the increasing of Cr content and cannot be seen within the Ni-Cr-Fe samples. The schematic drawing of oxidation behavior of Ni-Cr alloys is shown in Fig. 20.

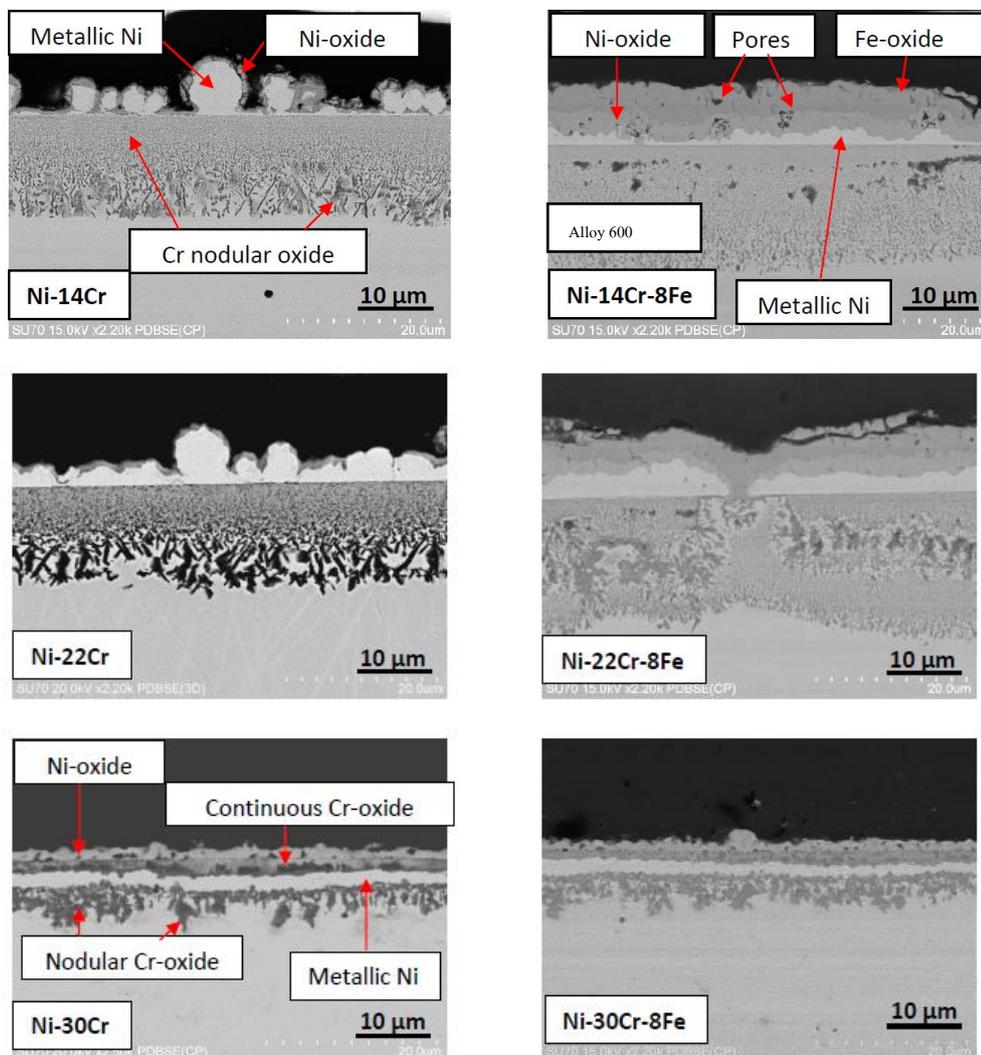

Fig. 19 SEM micrographs of metallographic cross-section of for mirror polished specimens exposed to superheated steam at 700 °C for 500 hr [39]

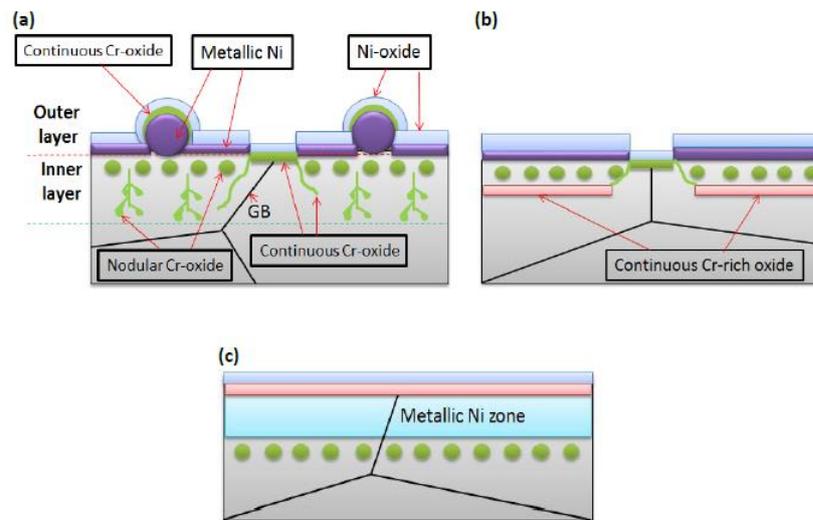

Fig. 20 Schematic representation of the oxidation behavior of Ni-Cr model alloys exposed to superheated steam at 700°C for 500 hr as a function of Cr-content in Ni-xCr: (a)  $x < 24$  wt.%, (b)  $24 \leq x \leq 26$  wt.% and (c)  $x > 26$  wt.%. [39]

Alloy 600 is a standard material used for steam generator tube in primary coolant circuit of pressurized water reactor (PWR) for nuclear power plant. It provides a good tolerance to general corrosion and pitting. Yang et al. [44] study the operating temperature and pH which affect alloy 600 material. Table 7 shows the composition of the alloy 600. Boron (B) and Lithium (Li) are used as the neutron absorber and pH control of the reactor coolant respectively. From Fig. 21, the open circuit potential (OCP) is significantly decreased by the increasing of operating temperature, but slightly decreases with the increasing of pH at the same temperature.

Table 7 Chemical composition of Alloy 600 (wt%) [44].

| Alloy | Ni     | Cr     | Fe    | Mn    | Si    | C     | Cu    | S     |
|-------|--------|--------|-------|-------|-------|-------|-------|-------|
| 600   | 73.593 | 16.040 | 9.020 | 0.200 | 0.310 | 0.071 | 0.045 | 0.001 |

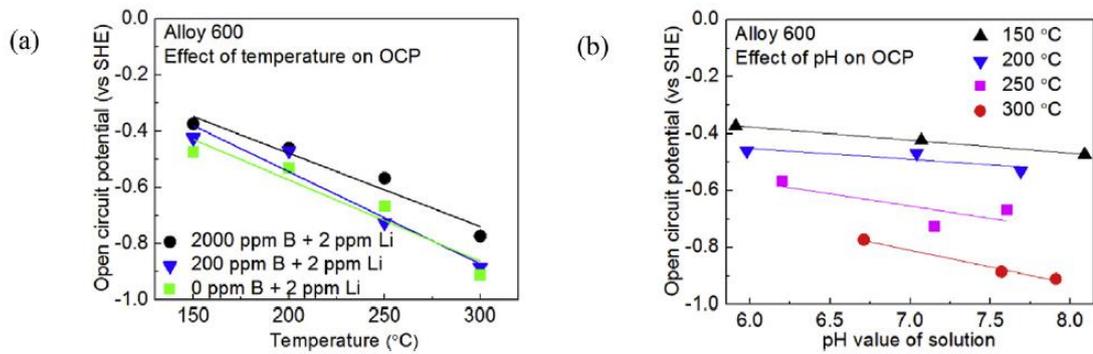

Fig. 21 The effect of (a) temperature and (b) pH for Alloy 600 on OCP [44].

The effect of temperature on the absolute impedance was also studied. The increasing of temperature reduces the impedance as see in Fig. 22. This indicates the improvement of corrosion resistance with the increased temperature.

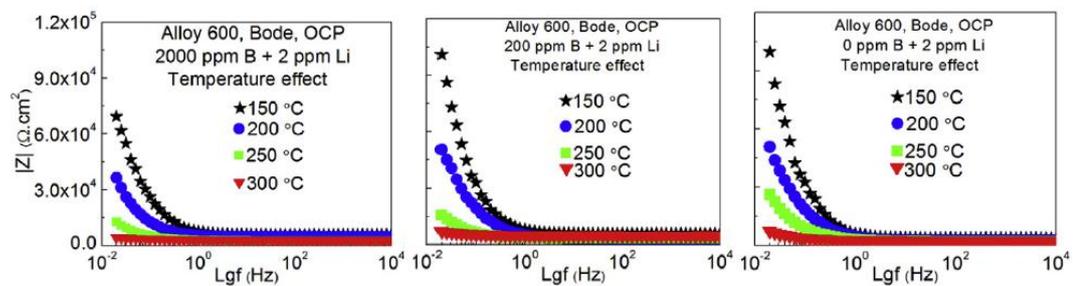

Fig. 22 The effect of temperature on the absolute impedance [44].

## Chapter III

### Experimental

#### 3.1. Material and powder preparation

Starting powder for hydrogen electrode was prepared. The compositions of the Ni-Cr-Fe/YSZ were varied with a constant ratio of total metal to YSZ (wt%) at 60:40. For Ni<sub>x</sub>-Fe<sub>1-x</sub>/YSZ and Ni<sub>x</sub>-Cr<sub>1-x</sub>-YSZ, x was in a range of 0-20 wt% as shown in Table 8. It should be noted that in Sample 9 (Ni-Fe-Cr/YSZ), the Fe-Cr composition was chosen following a composition of SOFC's interconnect [7] and steam-corrosion resistance tube [39]. To prepare the starting powder, NiO (Sigma-Aldrich, USA) and metal (Cr50/Ni50, CRO26010/2, Sigma-Aldrich, USA or Fe50/Ni50, Fe076020/1, Sigma-Aldrich, USA) were mixed in ethanol. The mixture was ball-milled for 24 hr to form a uniform slurry, followed by drying and grinding. Polyvinylpyrrolidone (PVP10) was introduced to modify the strength of Ni alloy based electrode [45]. The amount of PVP 10 was 5 %vol/vol in ethanol.

## 3.2. Cell fabrication

### 3.2.1. Fabrication of a conventional SOEC

Conventional Ni-YSZ was prepared by dry pressing method. 10 wt% of starch powder was added as a pore former to form an adequate porosity of porous cathode (Ni-YSZ at 60:40 wt%) [46]. The mixed powder was pressed into a disc with diameter of 2.54 cm under of 10 MPa for 30s. The green disc was pre-sintered at 1,100 °C for 2 hr. Then, electrolyte was deposited on one side of the pre-sintered cathode using dip-coating technique. The other side of electrode was covered by the plastic tape. The electrolyte slurry composition is shown on Table 9. After depositing electrolyte, the cell was sintered at 1,450 °C for 4 hr to form dense layer of YSZ. The  $Ba_{0.5}Sr_{0.5}Co_{0.8}Fe_{0.2}O_{3-\delta}$  (Kceracell, Republic of Korea) was used as an oxygen electrode which was deposited using doctor blade technique and sintered at 950 °C for 2 hr to

form a thin layer on the sintered YSZ with an effective area of  $0.5 \text{ cm}^2$ . The oxygen electrode slurry was made by mixing BSCF powder with alpha terpineol at the weight ratio of 1:1. The flow diagrams were shown in Fig. 23-25.

### **3.2.2. Fabrication of SOEC having Ni-alloy as a component in cathode**

To prevent oxidation of Ni in cathode under high steam partial pressure, the SOEC having Ni alloy containing cathode was fabricated. The cell fabrication was divided into 3 types having different cathodes: 1) The cathode was fabricated from Ni-alloys/YSZ powder; 2) The cathode was fabricated from Ni-alloys washed coated Ni-YSZ powder; and, 3) The fabricated Ni-YSZ cathode was impregnated by Ni-alloys.

### **3.2.3. Fabrication of SOEC having Ni-alloy /YSZ cathode**

Sample 1-8 were used to fabricate the Ni-based alloy cathodes (Ni-Fe/YSZ or Ni-Cr/YSZ) by dry pressing. For cathode-supported cell, the mixed powder was pressed into a disc with diameter of 2.54 cm under of 10 MPa for 30s, similar to the conventional SOEC in 3.2.1. The green disc was pre-sintered at 1,100 °C for 2 hr. For electrolyte-supported cell, the electrolyte disc was prepared by pressing YSZ powder into a disc and then sintered at 1,450 °C for 4 hr. The powders (Table 8) were mixed with the alpha terpineol (Sigma-Aldrich, USA) in the weight ratio of 1:1 to form a cathode slurry. The cathode slurries were then painted by doctor blade technique on the electrolyte. For oxygen electrode in the electrolyte-supported cell, platinum paste (70 wt% Pt loading, Nexceris, USA) was used and painted in the same way as the cathode.

#### **3.2.3.1. Fabrication of SOEC having the cathode fabricated from Ni-alloy washed coated Ni-YSZ powder**

Alternative method to prevent the oxidation while minimizing thermal expansion issue was used. Ni-YSZ powder were wash-coated by Ni-alloy slurry before fabricated into the cathode. The sintered Ni-YSZ was wash-coated by the alloy slurry. The slurry was prepared with the same composition as electrolyte slurry, presented in

Table 9, except Ni alloy powder was used instead of YSZ. Ni-alloy: containing 72 wt% Ni, 14-16 wt% Cr and 6-10 wt% Fe (66 wt% Ni, 30 wt% Cr and 4 wt% Fe confirmed by XRF) with the ratio of Ni alloy to YSZ at 60:40 wt%. This composition of alloy is called Alloy 600. It is generally used to prevent steam oxidation in various kind of work [39, 44]. The slurry was stirred with Ni-YSZ powders, 100°C 4 hr. Then the wash-coated powder was dried in the oven at 110 °C for 24 hr.

### 3.2.3.2. Fabrication of SOEC having Ni-alloy impregnated Ni-YSZ cathode

Alternative method was to introduce Ni-alloy composition after the cell was fabricated. Ni-YSZ cathode in the fabricated cell was impregnated by Ni alloy slurry. It was relatively more simple method, especially when considering that the starting powder containing Ni alloy composition was rather difficult to be fabricated. The slurry was prepared by using the same Ni alloys loading as the wash-coated technique. The loading was 1.71 mg Ni alloys-YSZ per cm<sup>2</sup>.

### 3.3. Characterization

The oxidation resistances were studied by thermogravimetric analysis (TGA, TA Instruments SDT Q600). The metal alloy/YSZ electrodes were tested under extremely condition in air at operating temperature of 800 °C. Before TGA measurement, the starting powder was reduced under 30%H<sub>2</sub>/N<sub>2</sub> at 800°C for 2 hr to convert metal oxide into metal. The degree of oxidation [35] can be calculated from weight gain of the sample as presented in equation (7).

$$\text{Degree of oxidation (t)} = \frac{m_{(t)} - m_{\text{Ni-YSZ}}}{m_{\text{NiO-YSZ}} - m_{\text{Ni-YSZ}}} \quad (7)$$

Where  $m_{\text{Ni-YSZ}}$  is the initial mass of the reduced sample,  $m(t)$  is the mass of the sample at time  $t$  during the oxidation and  $m_{\text{NiO-YSZ}}$  is the mass of fully oxidized sample.

The binding energies of samples were observed by x-ray photoelectron spectra (XPS, Kratos Analytical - AMICUS) using Mg anode emission 20 mA, Accel HT 10 kV.

The Sample crystallite characteristic was performed by X-ray diffraction (XRD, Brunker D8 Advance powder X-ray diffractometer) with a Cu-target X-ray tube (40 kV/m 30 mA) and angle of  $2\theta$  range from 20 - 80 degree (scan step 0.02°). The crystallite sizes were calculated by the Scherrer equation (2).

$$B(2\theta) = \frac{K\lambda}{L \cdot \cos\theta} \quad (8)$$

Where  $L$  is crystallite dimension,  $B$  is the peak width in radians,  $\theta$  is the Bragg angle and  $K$  is a Scherrer constant.

Temperature programmed reduction (TPR, micromeritics chemisorp 2750 pulse chemisorption system) was performed. In the experiment, 0.05 grams of the sample was placed in a quartz tube and preheated at 300 °C in a flow of nitrogen before further heated to 850 °C with a heating rate of 10 °C/minhr under a flow of 10% H<sub>2</sub>/argon.

Morphology of electrodes was analyzed by scanning electron microscope (SEM, Hitachi S-3400N JEOL model S-3400). The magnification used is range from 800 to 5000 times.

### 3.4. Electrochemical performance measurement

Single cell polarization curves were generated using linear sweep techniques. A potentiostat/gavanostat (Metrohm Autolab, Utrecht, The Netherlands) was used to control the voltage between 0.5 and 1.8 V with a scan rate of 20 mV/s. Electrochemical impedance spectroscopy (EIS) measurements were functioned using a sinusoidal signal amplitude of 20 mV<sub>rms</sub>, across the frequency range of 100 kHz to 0.1 Hz. The equivalent circuit for the impedance response fitting is shown in Fig. 26. The feed contained humidified hydrogen at cathode chamber using varied steam to hydrogen (60:40, 70:30 and 80:20) when operating temperature was maintained at 800 °C (see Table 10).

The electrical connection was made to the cell electrodes via platinum wires and paste. The cell ridge was sealed using gas sealant (Ceramabond 552, Aramco, Houston, TX, USA) to create a separation of the gas environment of two electrodes. Fig. 27 shows the experimental set-up for the delivery of the gas to the cell in the furnace. The feed of H<sub>2</sub>, H<sub>2</sub>O and N<sub>2</sub> with various of composition were allowed to be introduced to the H<sub>2</sub> electrode. N<sub>2</sub> was used to balance the gas flow and control the steam ratio in the gas compositions. Deionized water was transferred using an HPLC liquid pump (Teledyne SSI, State College, PA, USA). Steam was generated in a heated tube and mixed with the N<sub>2</sub> and H<sub>2</sub> lines.

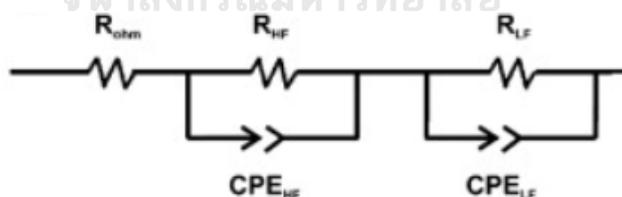

Fig. 26 Equivalent circuit for impedance response fitting [47]

Table 10 steam to H<sub>2</sub> ratio of operating condition

| Steam to H <sub>2</sub> ratio | H <sub>2</sub> flow (ml/min) | N <sub>2</sub> flow (ml/min) | Steam flow (ml/min) | Total flow (ml/min) |
|-------------------------------|------------------------------|------------------------------|---------------------|---------------------|
| 60:40                         | 20                           | 100                          | 30                  | 150                 |
| 70:30                         | 20                           | 83                           | 47                  | 150                 |
| 80:20                         | 20                           | 50                           | 80                  | 150                 |

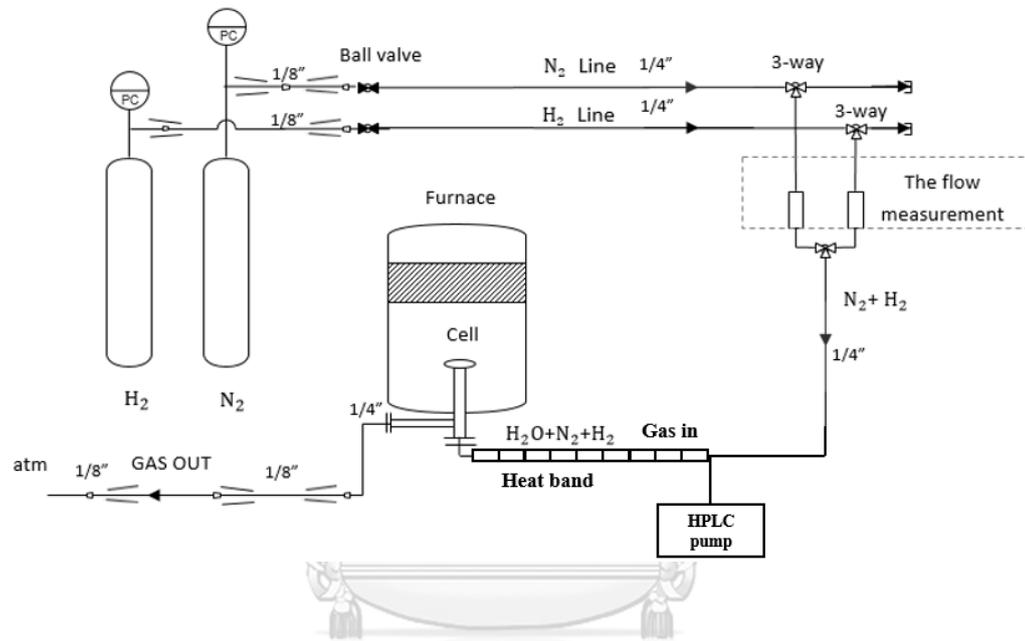

Fig. 27 Schematic drawing of the test system

The open circuit voltages (OCV) are calculated by Nernst equation [48, 49] expressed by equation (3)

$$E = E^0 - \frac{RT \ln \left( \frac{p_{H_2O}}{p_{H_2} \sqrt{p_{O_2}}} \right)}{nF} \quad (9)$$

when  $E$  is the cell potential at the interested temperature,  $E^0$  is the standard cell potential,  $R$  is the universal gas constant ( $8.314 \text{ JK}^{-1}\text{mol}^{-1}$ ),  $T$  is the temperature in

kelvins,  $n$  is the number of electron transferred and  $F$  is Faraday constant ( $96485 \text{ C mol}^{-1}$ ) The calculated OCV of 70:30 steam to hydrogen ratio at each operating temperature are shown in Table 11. The calculated OCVs were corresponded with Chiodelli and Malavasi [50]

Table 11 The calculated OCV at operating temperature

| Operating temperature, °C | Calculated OCV, V |
|---------------------------|-------------------|
| 650                       | 0.95              |
| 700                       | 0.94              |
| 750                       | 0.92              |
| 800                       | 0.90              |
| 850                       | 0.88              |
| 900                       | 0.87              |

## Chapter IV

### Result and discussion

#### 4.1. Thermogravimetric analysis (TGA)

The oxidation resistance was observed using TGA. Figs 28(a) and 28(b) show the degree of oxidation of the binary metals and ceramic (Ni-Fe/YSZ and Ni-Cr/YSZ), comparing to conventional Ni-YSZ. Increasing Fe content significantly reduced oxidation rate of the cathode. It should be noted that when increasing Fe content, Ni content decreased. Fe was reported to exhibit a higher oxidation tolerance than Ni [38]. For Ni-Cr/YSZ, increasing Cr content decreased oxidation tolerance. However, 5 wt% Cr addition decreased the oxidation resistance of the cathode when compared to conventional Ni-YSZ. Hamdani [39] also reports the fluctuation trends in weight gain measurement For Ni Cr alloys. In this study, the oxidation tolerance of 0-30 wt% Cr loading in Ni-Cr alloys are studied. Ni-26Cr of mirror and electro polished demonstrates the best oxidation resistance. Fig. 28(c) and (d) show the degree of oxidation of Alloy 600-YSZ compared to conventional Ni-YSZ in air atmosphere at 800 °C and ramping from room temperature-800 °C, respectively. There was no difference was seen between both electrode at 800 °C due to severe oxidation condition. However, it can be seen in Fig. 28(d) when the temperature was ramp from room temperature to 800 °C, Ni alloy-YSZ exhibited relatively higher oxidation resistance than the conventional Ni-YSZ.

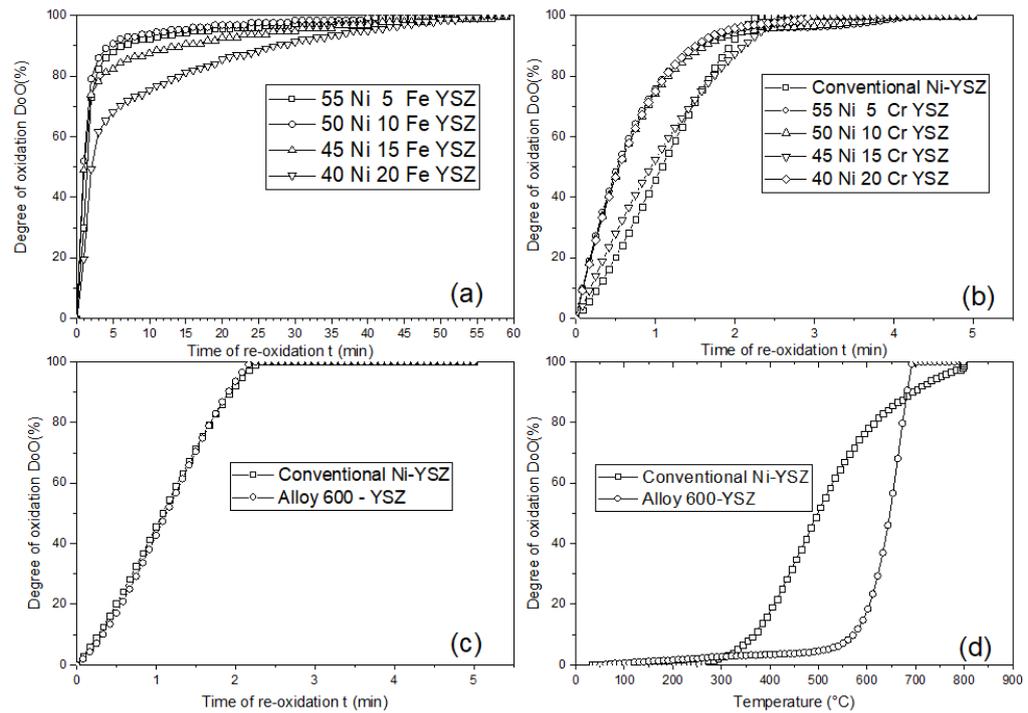

Fig. 28 Degree of oxidation (%) of: (a) Ni-Fe-YSZ; (b) Ni-Cr-YSZ; (c) Ni alloy: containing 72 wt% Ni, 14-16 wt% Cr and 6-10 wt% Fe with the ratio of Ni alloy to YSZ at 60:40 wt% compared to conventional Ni-YSZ in air atmosphere at 800 °C; and, (d) Ni alloy-YSZ compared to conventional Ni-YSZ in air atmosphere from room temperature – 800 °C.

CHULALONGKORN UNIVERSITY

#### 4.2. X-ray photoelectron spectra (XPS)

The starting powder of hydrogen electrode was characterized by XPS. Fig. 29 shows the valence state of Ni  $2p_{1/2}$ , Ni  $2p_{3/2}$ , Cr  $2p_{3/2}$  and Fe  $2p_{3/2}$  of NiCr-YSZ) and NiFe-YSZ. The XPS of Ni  $2p_{1/2}$  and Ni  $2p_{3/2}$  spectra can be distinguished into 4 peaks as can be seen in Fig 29(a) and 29(b) for NiCr-YSZ and NiFe-YSZ, respectively. The negative shift refers to the lower electronegativity of the chromium and iron ion. As presented in Fig. 29(c), the peak position of the Cr  $2p_{3/2}$  spectra from 5, 10, 15 and 20 wt% Cr

were 578.3, 577.8, 576.9 and 577.3 eV, respectively. The binding energy peak position of the Cr  $2p_{1/2}$  spectra from 5, 10, 15 and 20 wt% Cr were 588.4, 587.5, 586.7 and 586.2 eV, respectively. The valence state at lower and higher Cr loading were identified as  $Cr^{6+}$  and  $Cr^{3+}$ , respectively. Fig. 29(d) show the XPS of  $Fe2p_{3/2}$  spectra. The peaks were unclear in the low Fe composition (5 wt%). The binding energy peak positions of the Fe  $2p_{3/2}$  spectra were around 710 to 715 eV, indicating a  $Fe^{3+}$ . The reference of binding energy peak positions of Cr and Fe were obtained from the study of Sainio et al. [51] and Yamashita et al. [52], respectively.

Then the deconvolution of Cr spectra was plotted and shown in Fig. 30. The peaks at 577.4 and 579.9 eV in  $Cr2p_{3/2}$  can be assigned to  $Cr^{3+}$  and  $Cr^{6+}$ , respectively. The peaks at 586.9 and 588.9 eV in  $Cr2p_{1/2}$  can be assigned to  $Cr^{3+}$  and  $Cr^{6+}$ , respectively. As seen in Table 12, the ratio of  $Cr^{6+}/Cr^{3+}$  decreased with the increasing of Cr content. The electronic conductivity may increase with increasing ionic radius [53]. The deconvolution of Fe spectra was undefined due to the low amount of Fe content. Then, Ni spectra was deconvoluted as seen in Fig. 31. The intensity of NiFe sample was higher than the NiCr sample. The metallic Ni peaks were found at 874.9 eV. The others were identified as a  $Ni^{2+}$ . After that the compositions of Ni-Fe-Cr/YSZ were calculated from the integrated area of XPS peaks. The data was shown in Table 13. Ni has a lower content than the expectation while YSZ was higher. This indicates that the prepared powders were not homogeneously mixed.

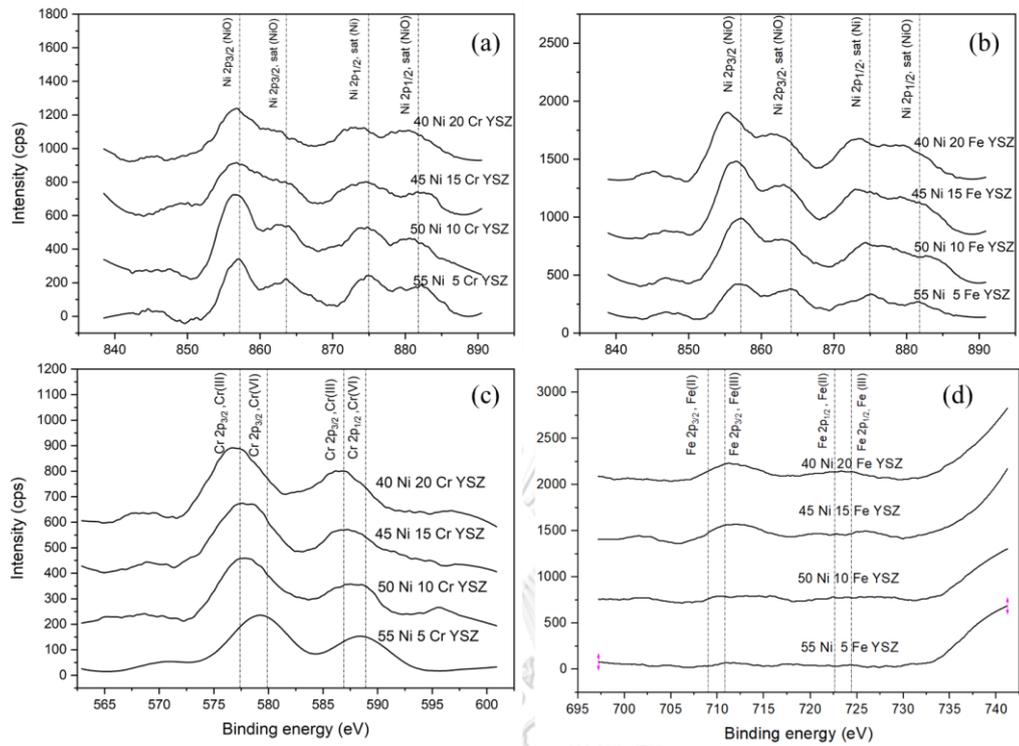

Fig. 29 The XPS of different Fe and Cr loading Ni-YSZ electrodes: (a) Ni spectra of NiCr-YSZ; (b) Ni spectra of NiFe-YSZ; (c) Cr 2p<sub>3/2</sub> spectra of NiCr-YSZ and (d) Fe 2p<sub>3/2</sub> spectra of NiFe-YSZ

### 4.3. X-ray powder diffraction (XRD) and X-ray Fluorescence analysis

XRD patterns of sintered NiCr-YSZ and NiFe-YSZ cathode having various Cr or Fe loading from 0 to 20 wt% (sintered at 1,100 °C for 2 hr) are presented in Fig. 32(a) and 31(b). A low-intensity peak of NiCr<sub>2</sub>O<sub>4</sub> were detected in NiCr-YSZ (Fig 32(a)) while NiFe<sub>2</sub>O<sub>4</sub> were detected in NiFe-YSZ (Fig 32(b)). In NiFe-YSZ sample, segregated Fe<sub>2</sub>O<sub>3</sub> was also observed after the heat treatment. Similarly, the XRD pattern of alloy 600-YSZ also showed Fe<sub>2</sub>O<sub>3</sub> phase. The peak location was corresponding well with the work of Qi [54]. The formation of NiFe<sub>2</sub>O<sub>4</sub> in Ni-Fe system was also reported by Fiuza et al [55]. For 20Fe15Ni/YSZ-GDC and 30Fe5Ni/YSZ-GDC composition, the peaks at 43.6° 50.84° and 74.69° was suggested as Ni-Fe alloy with an FCC structure. The crystallite size was calculated by Scherrer equation (Eq.(8)). The average crystallite sizes of NiCr-YSZ with Cr loading from 0 to 20 wt% were 47.14 53.72 65.40 and 66.12 nm, respectively. The average crystallite size of NiFe-YSZ with Fe loading from 0 to 20 wt% were 36.65 37.49 43.06 and 51.39 nm, respectively. The average crystallite size was increased with the increasing of alloy content.

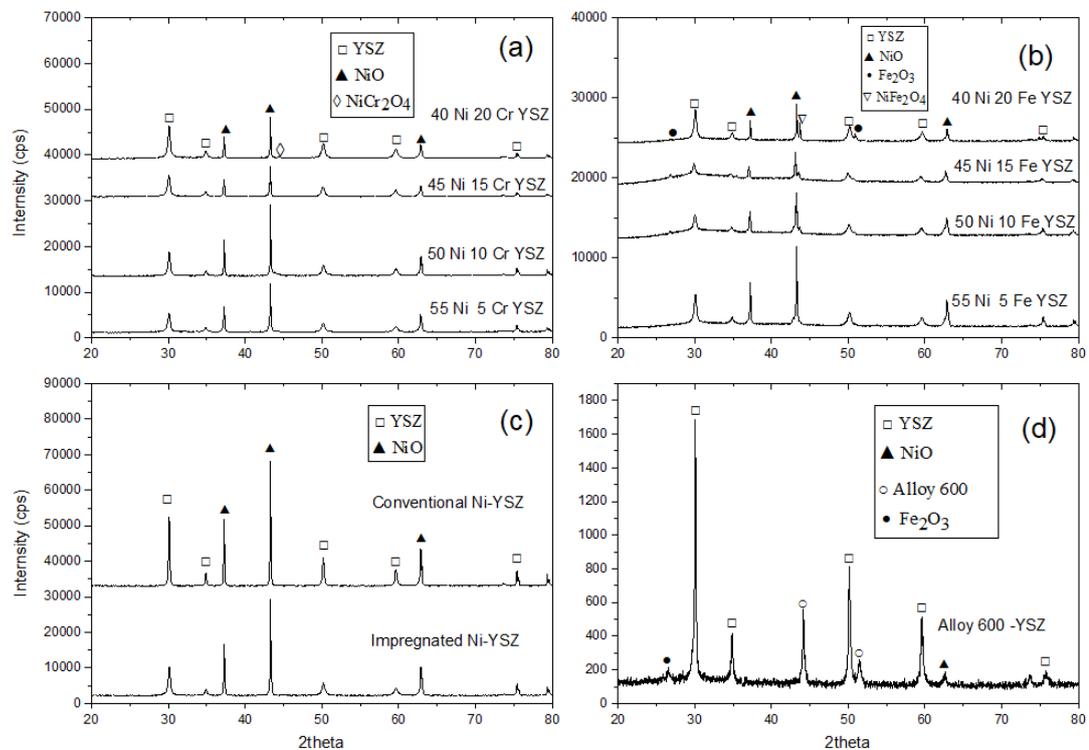

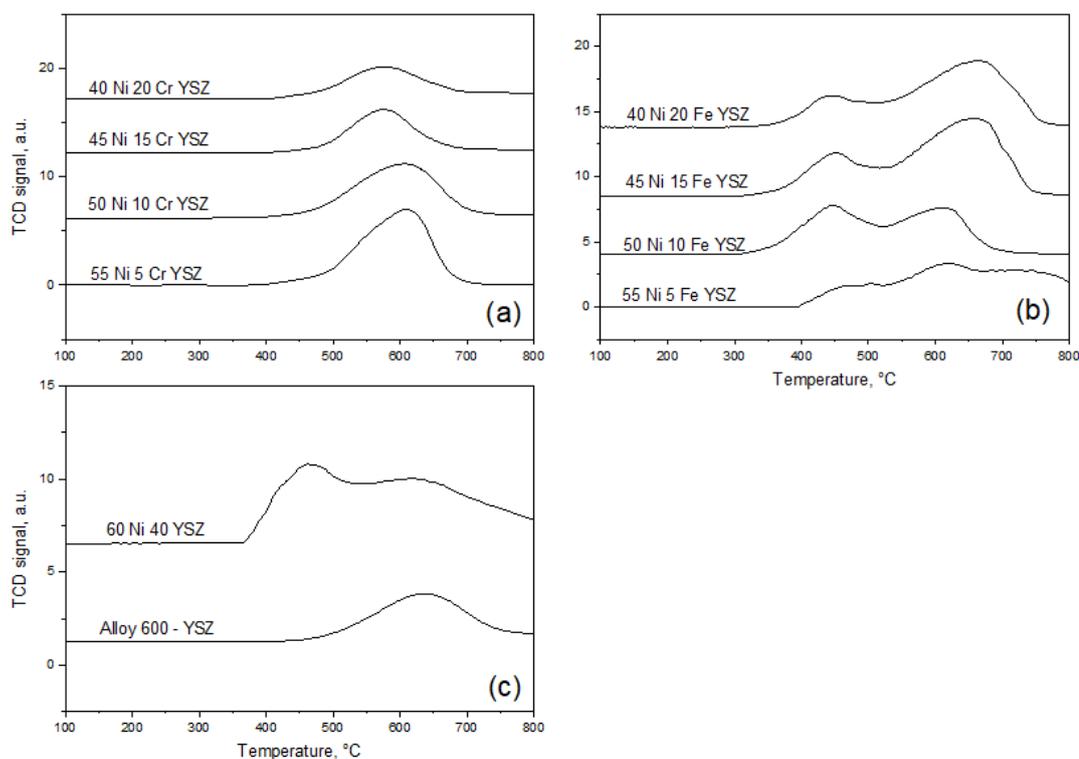

Fig. 32 pattern of sintered powder at 1,100 °C for 2 hr of (a) NiCr-YSZ (b) NiFe-YSZ (c) Impregnated Ni-YSZ compared to conventional Ni-YSZ and (d) Alloy 600-YSZ[56]

Figure 32(c) shows the XRD patterns of Ni alloys impregnated Ni-YSZ while Fig. 32(d) shows the XRD pattern of alloy 600-YSZ. The alloys peak was not detected. This may be caused by low amounts of Ni alloy loading and a well-mixed with YSZ forming a composite. The crystallite size of Ni alloys impregnated Ni-YSZ, Alloy 600-YSZ and conventional Ni-YSZ were 53.54 34.64 and 60.16 nm respectively. The alloys loading reduced the size of crystallite.

#### 4.4. Hydrogen Temperature programmed reduction (H<sub>2</sub>-TPR) analysis

The reducibility of NiCr-YSZ and NiFe-YSZ powders was investigated by hydrogen temperature programmed reduction (H<sub>2</sub>-TPR). Fig. 33(a) and 33(b) show the H<sub>2</sub>-TPR profiles of NiCr-YSZ and NiFe-YSZ, respectively. No peaks were detected at temperature below 400 °C. NiCr-YSZ samples exhibited only one reduction peak at around 500 to 700 °C, corresponding well with other work [57]. The peaks shift to the lower temperature when increasing the Cr content as seen in Fig. 33(a) [58]. The single dominant peak indicated that all the Cr<sup>6+</sup> species were reduced into the oxidation state of Cr<sup>3+</sup>. No further reducibility was found due to the Cr<sub>2</sub>O<sub>3</sub> is the most difficult oxide to reduce into metallic Cr [59]. The reduction peaks of 5 wt% to 20 wt% Cr loading are located at 609, 605, 576 and 575 °C respectively.

*Fig. 33 Hydrogen TPR profile of cathode starting powder with different Cr or Fe loading from 5 to 20 wt%, sintered at 1,100 °C for 2 hr: (a) NiCr-YSZ and (b) NiFe-YSZ and (c) conventional Ni-YSZ and alloy*

For NiFe-YSZ samples, there were two reduction peaks. All sample showed the first and second reduction peak around 400 °C and above 600 °C, respectively. According to Al-Dossary et al. [60], The  $\text{Fe}_2\text{O}_3$  can be reduced into two or even three steps. The reduction sequence is as follow:  $\text{Fe}_2\text{O}_3 \rightarrow \text{Fe}_3\text{O}_4 \rightarrow [\text{FeO}] \rightarrow \text{metallic Fe}$

The first step takes place around 400 °C. It is a reduction of  $\text{Fe}_2\text{O}_3$  (hematite) into  $\text{Fe}_3\text{O}_4$  (magnetite). For the second peak is a reduction into FeO and metallic Fe phase which might coexist. High Fe loading increased the reduction temperature, corresponding to other work [61]. It should be noted that from the TGA result, increase Fe content also increased oxidation tolerance (Fig 28(a)). The first peak of 5 wt% to 20 wt% of Fe loading were located at 466, 449, 451 and 449 °C, respectively. The second peak of 5 wt% to 20 wt% of Fe loading were located at 623, 624, 658 and 669 °C, respectively. For conventional Ni-YSZ, The TPR profiles were in a broad range of 300 to 600 °C [62].

#### 4.5. Scanning electron microscope (SEM)

When fabricating the hydrogen electrode directly from Ni alloy-YSZ starting powder, it was very difficult to fabricate the cell. Polyvinylpyrrolidone (PVP10) was introduced to modify the strength of Ni alloy electrode [45]. The amount of PVP 10 added is 5 %v/v of ethanol. Then the electrodes were sintered at 1,100 °C for 2 hr, using 5 °C/min. The morphology of sintered hydrogen electrodes was shown on Fig. 34. The particle alignment and uniformity of NiCr-YSZ seemed better than NiFe-YSZ. Fabricated cathode from NiFe-YSZ was crack and therefore was not suitable for

electrolyte deposition. For NiCr-YSZ cathode, the particle was packed with the increasing of Cr loading. However, all NiCr-YSZ cathode was fragile and brittle. The study of Lopes et al. [63] shows that the metal-ceramic (Ni-Cr alloys -ceramic) bond strength is affected by the CTE. The high difference of CTE can leads to the bonding fail. After that the compositions of sample were obtained from EDX as seen in Table 14. This results also confirmed that the ball-milling's time was not enough to get the well mixed slurry. The conventional Ni-YSZ electrode has a bigger size particle compared to the impregnated electrode. Then, the morphology of Ni alloys wash-coated Ni-YSZ electrode was shown in Fig.34(k). The particles were formed into a dense grain which was not suitable to use as a cathode due to the lack of TPBs.

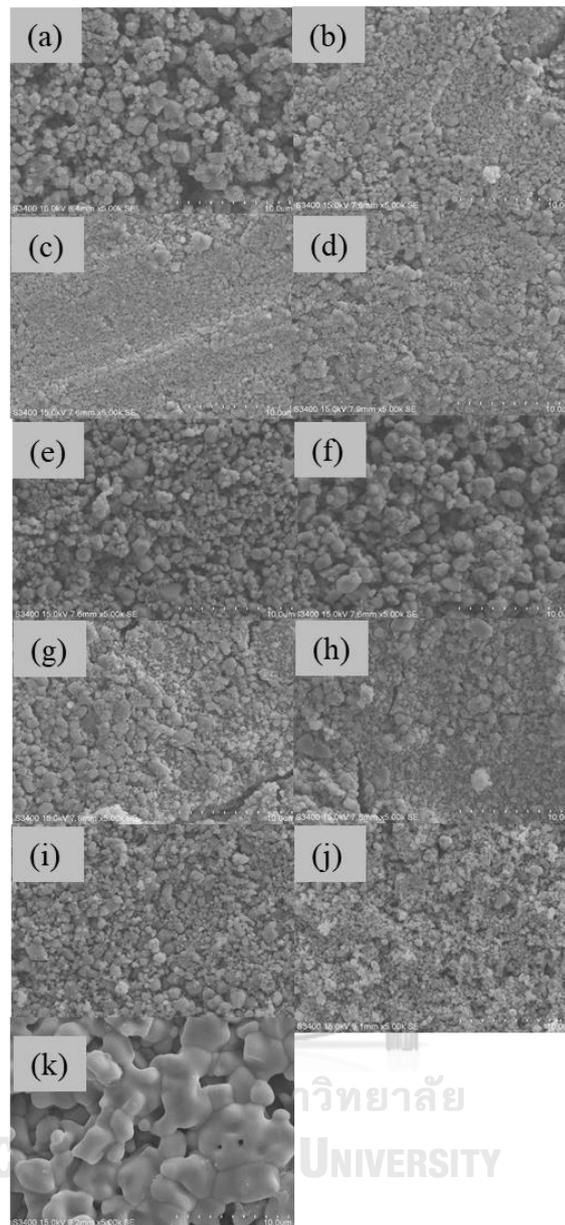

Fig. 34 SEM images at 5000X magnification of various Ni-Fe-Cr content in cathode sintered at 1100 °C for 2 hr, (a-d) sintered hydrogen electrode containing 5 to 20 wt% Cr, respectively, (e-h) sintered hydrogen electrode containing 5 to 20 wt% Fe, respectively, (i) sintered conventional electrode, (j) sintered Ni-alloys impregnated electrode and (k) sintered Ni alloys wash-coated electrode.

Table 14 Composition of Ni-Fe-Cr-YSZ obtained from SEM-EDX

| Composition     | Ni(wt%) | Cr (wt%) | Y (wt%) | Zr (wt%) |
|-----------------|---------|----------|---------|----------|
| 55 Ni 5 Cr YSZ  | 58.46   | 4.99     | 3.32    | 33.22    |
| 50 Ni 10 Cr YSZ | 42.56   | 4.19     | 5.83    | 47.43    |
| 45 Ni 15 Cr YSZ | 38.50   | 7.92     | 5.69    | 47.88    |
| 40 Ni 20 Cr YSZ | 20.93   | 13.67    | 7.30    | 58.1     |

| Composition     | Ni (wt%) | Fe (wt%) | Y (wt%) | Zr (wt%) |
|-----------------|----------|----------|---------|----------|
| 55 Ni 5 Fe YSZ  | 50.25    | 1.18     | 5.55    | 43.02    |
| 50 Ni 10 Fe YSZ | 54.21    | 8.70     | 3.45    | 33.65    |
| 45 Ni 15 Fe YSZ | 37.15    | 14.44    | 5.92    | 42.49    |
| 40 Ni 20 Fe YSZ | 34.95    | 16.70    | 5.99    | 42.37    |

The fabrication of SOEC using direct Ni alloy-YSZ cathode as a support was not suitable due to its low strength and fragile property. However, for comparison of the electrochemical performance, YSZ electrolyte support cell was used. Electrolyte layer was fabricated using dry-pressing method and sintering at 1,450 °C for 4 hr using heating rate of 5 °C/min. The sintered electrolyte thickness was about 2 mm. Then the cathode was painted by using doctor's blade technique. The cathode slurries consist of Ni<sub>1-x</sub>Cr<sub>x</sub>-YSZ and Ni<sub>1-x</sub>Fe<sub>x</sub>-YSZ, when x is varying from 5 to 20 wt%, and using alpha terpineol at 1:1 ratio as a binder. The sintered electrode was presented in Fig 35. The thickness of cathode layer was about 25 μm.

After sintering the NiFe-YSZ/YSZ (electrolyte support) at 1,100 °C for 2 hr with heating rate of 5 °C/min, the cathode layer of NiFe-YSZ electrode was peel off due to the thermal expansion. The sintering electrode was shown in Fig. 35(e).

The Ni-alloy impregnated Ni-YSZ powder was fabricated into the cathode disc. The disc was easily to fabricate due to the lower content of the alloy. The sintering temperature was controlled by the same condition as conventional electrode. The undefined black dot appears as seen in Fig. 35(f). Phase change may occur at high sintering temperature of 1,100 °C. It is required for further investigation.

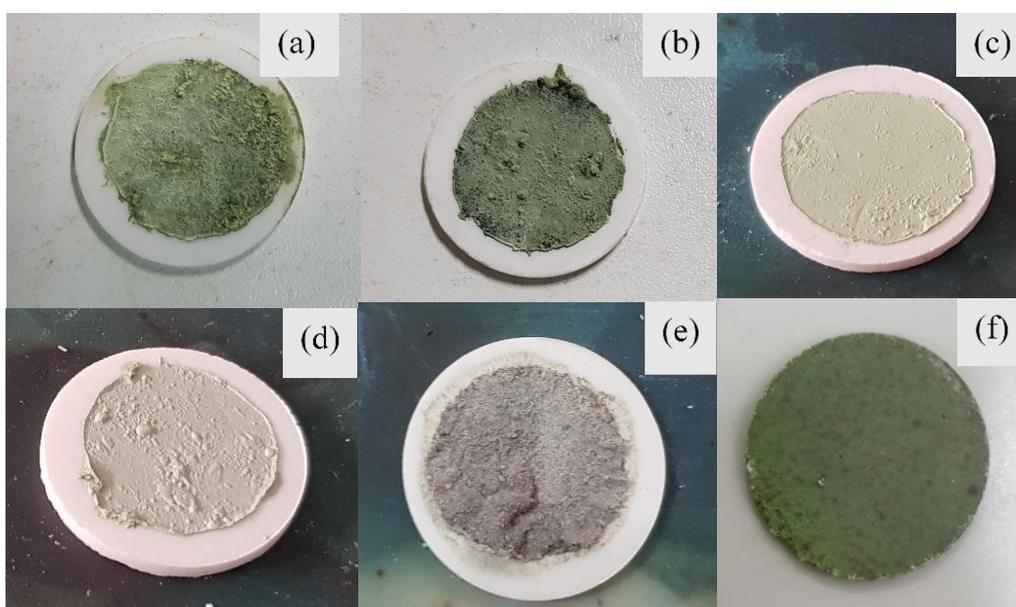

Fig. 35 Sintered hydrogen electrode on the electrolyte supporting layer at 1,100°C for 2hr, using 5 °C/min. (a-d) hydrogen electrode containing 5 to 20 wt% Cr respectively, (e) hydrogen electrode containing 5 %wt Fe loading , (f) Ni alloys impregnated Ni-YSZ cathode

The Alternative method to prevent the oxidation while minimizing thermal expansion issue was to impregnate conventional Ni-YSZ cathode with Ni alloy slurry. The impregnated slurry composition is shown in Table 9 but using Ni alloys instead of YSZ. The cross-sectional morphology of Ni-alloy impregnated Ni-YSZ/YSZ/BSCF before

and after electrochemical performance test was presented in Fig. 36. The impregnated layer was about 10.52  $\mu\text{m}$  thick.

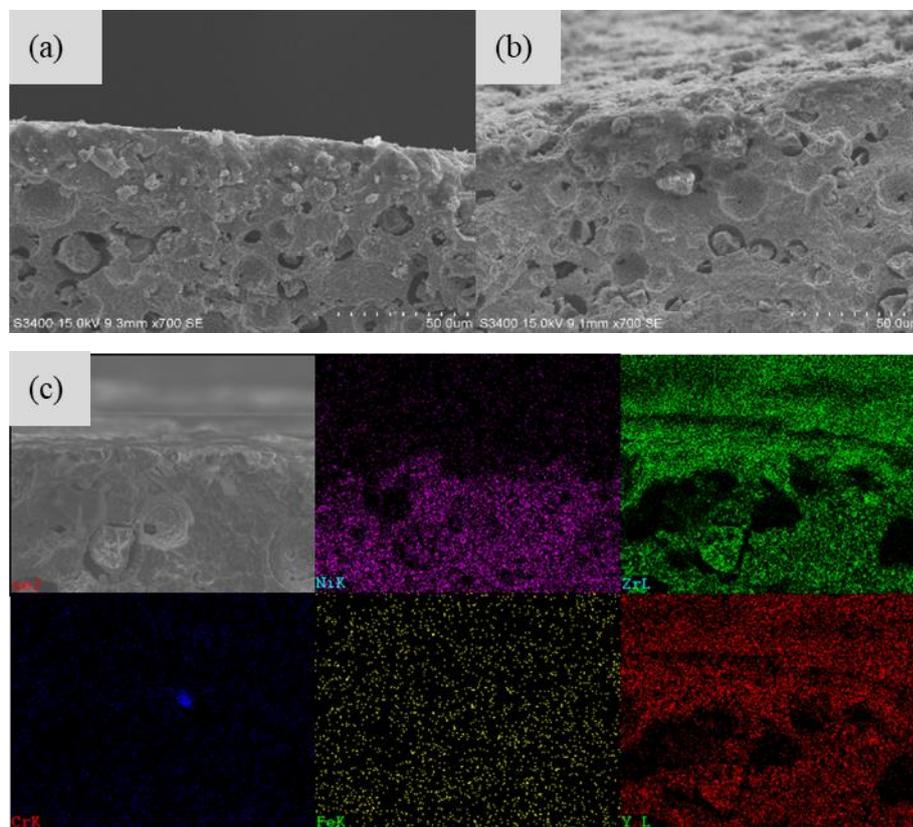

Fig. 36 SEM patterns at 700X magnification of Ni Alloy impregnated Ni-YSZ electrode (a) before and (b) after electrochemical performance test, and (c) the EDX mapping of Ni Alloy impregnated Ni-YSZ electrode

#### 4.6. Electrochemical performance

The electrochemical performance of electrolyte supported conventional Ni-YSZ/YSZ/Pt and NiCr-YSZ/YSZ/Pt of varying Cr contents from 0 to 20 wt% are shown in Fig. 37(a-e) respectively. The measured OCV was slightly lower than the theoretical OCV calculated using Nernst equation (Eq. (9)). The OCV decreased with the increasing of operating temperature.

The linear sweep technique was used to describe the single polarization when operating potential was controlled from 0.6 to 1.8 V. The highest current density was obtained from the 55Ni 5Cr-YSZ/YSZ/Pt at various operating temperature from 650 to 900 °C. The electrochemical performance significantly increased above 800 °C. The performance increased with the increasing operating temperature. Increasing Cr content in the cathode decreased the electrochemical performance of the cell. It was reported that Cr-containing alloys can form a layer of chromatic scale which can protect the material from heavy oxidation. However, thicker layer of the scale can reduce the conductivity and contact in electrode [64]. However, under high partial pressure of steam at elevated temperature, Cr was reported to volatile and deposit on the cathode, leading to a loss of oxidation tolerance [65]. The small amount of Cr was reported to improve the adsorption and increase catalytic active sites [36, 66]. The higher Cr loading, the lower electronic conductivity.

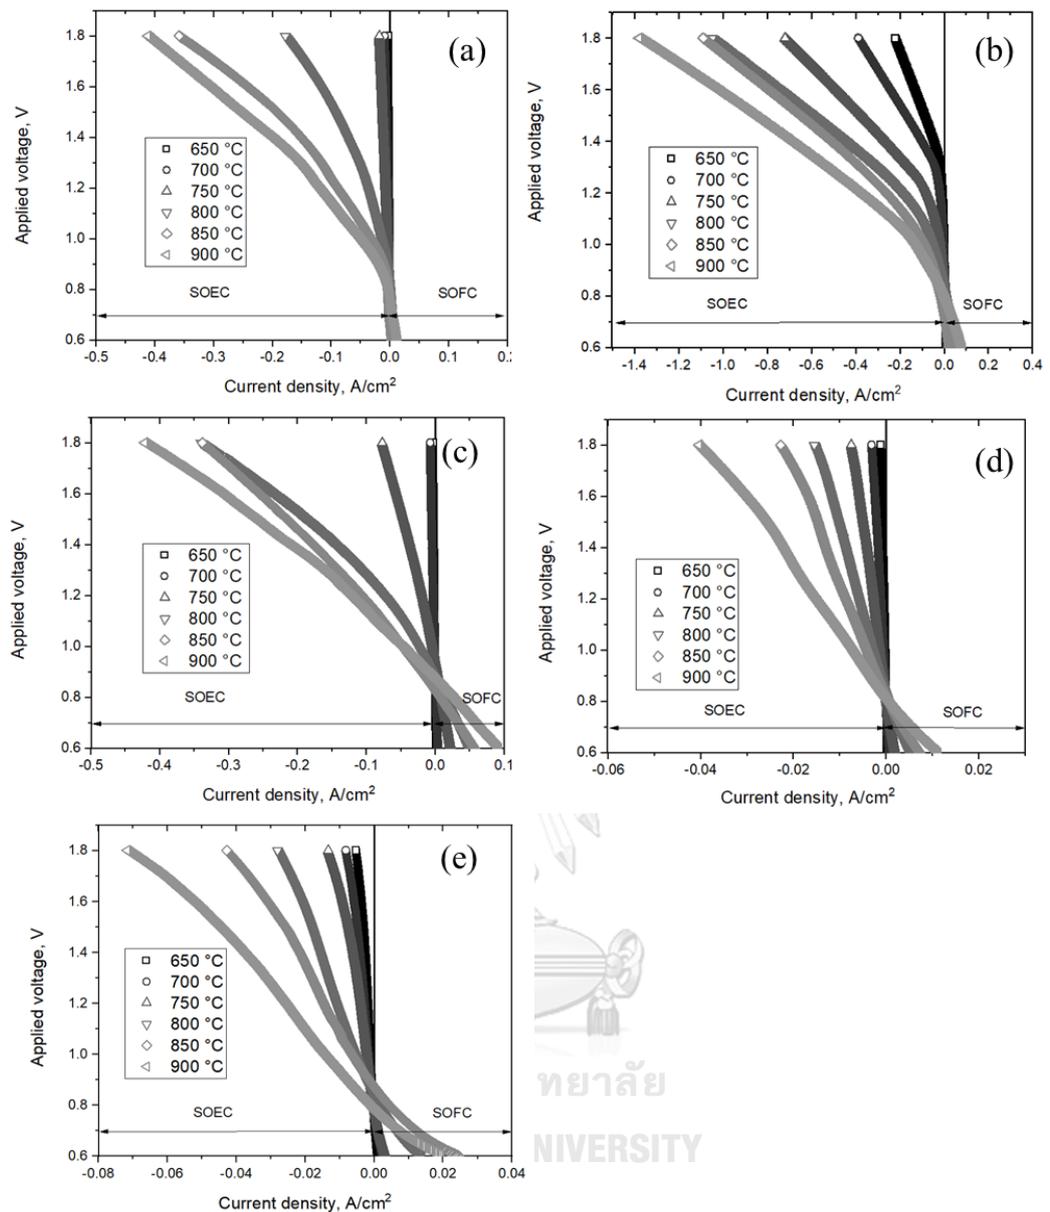

Fig. 37 Comparison of the electrochemical performance of various operating temperature and steam to  $H_2$  ratio at 70:30 of (a) electrolyte-supported conventional Ni-YSZ/YSZ/Pt and (b-e) electrolyte-supported NiCr/YSZ/Pt with varying Cr contents from 5 to 20 wt%, respectively

The comparison of I/V profiles and electrochemical impedance response at OCV of various Cr contents from 0 to 20 wt% at operating temperature of 800 °C controlled steam to hydrogen ratio at 70:30 is presented in Fig. 38(a) and 38(b)

respectively. The highest current densities at 1.8 V of electrolyte-supported conventional Ni-YSZ/YSZ/Pt and NiCr/YSZ/Pt with varying Cr contents from 5 to 20 wt% were -0.12 -1.05 -0.34 -0.03 and -0.02 A/cm<sup>2</sup>, respectively. For electrochemical impedance response,  $R_0$ ,  $R_{HF}$  and  $R_{LF}$  are referred to Ohmic resistance and polarization resistance in high frequency region and low frequency region, respectively. The small amount of Cr loading such as 5 and 10 wt %Cr can be confirmed that it decreased the polarization resistance (HF and LF region) as seen in Fig. 38(b). The Ohmic resistance and polarization in both HF and LF region are shown in the Table 15. The frequency about 1-10 Hz represents the gas diffusion in hydrogen electrode, 10-200 Hz represent the oxygen electrode process such as chemical surface exchange of O<sub>2</sub> and O<sup>2-</sup> bulk diffusion and a higher than 200 Hz represent charge transfer reaction and ionic transport in hydrogen electrode [67]. The addition of Cr loading should reduce the mass transport resistance due to the higher porosity while increase the activation resistance. The impedance arc cannot clearly distinguish these two characteristic resistances.

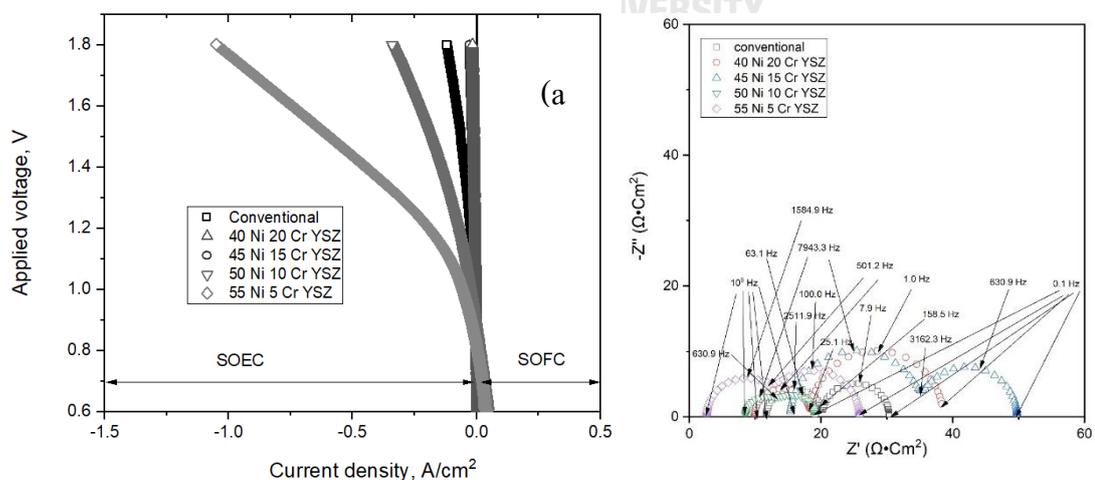

Fig. 38 Comparison of the electrochemical performance of various Cr contents from 0 to 20 wt% and steam to H<sub>2</sub> ratio at 70:30 of conventional at 800 °C (a) IV profiles and (b) electrochemical impedance response (EIS)

Table 15 Resistance of the various electrolyte support NiCr-YSZ/ YSZ/ Pt. R<sub>0</sub>, R<sub>HF</sub> and R<sub>LF</sub> are referred to ohmic resistance and polarization resistance in high frequency region and low frequency region, respectively.

| Composition                  | NiCr-YSZ/ YSZ/BSCF (electrolyte support) |   |   |                                 |

The electrochemical performance of Ni-alloys impregnated Ni-YSZ/YSZ/BSCF and conventional Ni-YSZ/YSZ/BSCF were compared as shown in Fig. 39(a). Both OCV were slightly lower than the calculated value using Nernst equation. The calculated OCV should be around 0.87 V at operating temperature of 800 °C under steam to hydrogen ratio of 70:30. The measured OCV of Ni alloys impregnated and conventional are 0.80 and 0.82 V respectively.

The effect of operating temperatures was investigated between 650 and 900 °C as shown in Fig. 39(b). Increasing temperature increased the cell performance. Conventional cell exhibited relative higher performance than the impregnated cell. At higher operating temperature, the conventional electrode exhibited a better performance. This can be caused by a better electrocatalytic activity of Ni at high operating temperature as well as higher electronic conductivity of Ni compared to Fe and Cr at higher operating temperature [68]. The highest current density at 1.8V and

800 °C of conventional Ni-YSZ/ YSZ/ BSCF and impregnated Ni-YSZ/ YSZ/ BSCF was -0.50 and -0.26 A/cm<sup>2</sup>, respectively.

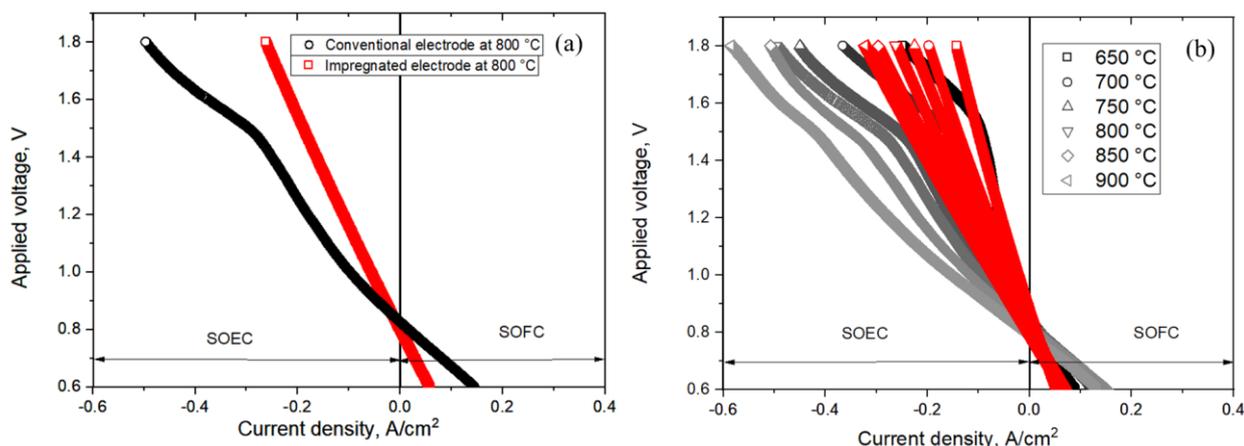

Fig. 39 Comparison of the electrochemical performance between (Red lines) Ni alloy impregnated Ni-YSZ/YSZ/BSCF electrode and (Black lines) conventional Ni-YSZ/YSZ/BSCF electrode using steam to H<sub>2</sub> ratio at 70:30: (a) at 800 °C and (b) from 650 °C to 900 °C

Fig. 40(a) shows a comparison of performance durability comparing between conventional Ni-YSZ/ YSZ/BSCF and Ni-alloys impregnated Ni-YSZ/YSZ/BSCF. After 48 hr of durability test, the impregnated Ni-YSZ/ YSZ/ BSCF shows lower degradation rate (0.7 mA/hr) than the conventional cell (0.9 mA/hr). Electrochemical impedance analysis is shown in Fig. 40(b). The resistances of the Ni alloy impregnated Ni-YSZ/YSZ/BSCF are shown in table 16. Ni alloy impregnated Ni-YSZ/YSZ/BSCF has higher ohmic resistance than conventional which may cause by the thickness of addition layer of impregnating. The resistance  $R_{HF}$  and  $R_{LF}$  of conventional electrode increase over operation time. But there are some fluctuation trends of obtained resistance from Ni alloy impregnated electrode. The  $R_{HF}$  trends to increase over time. However,  $R_{LF}$  trends to decrease. These can be caused by the agglomeration between Ni and alloys which

affects the activation resistance while increasing the porosity in the structure which lower the mass transport resistance.

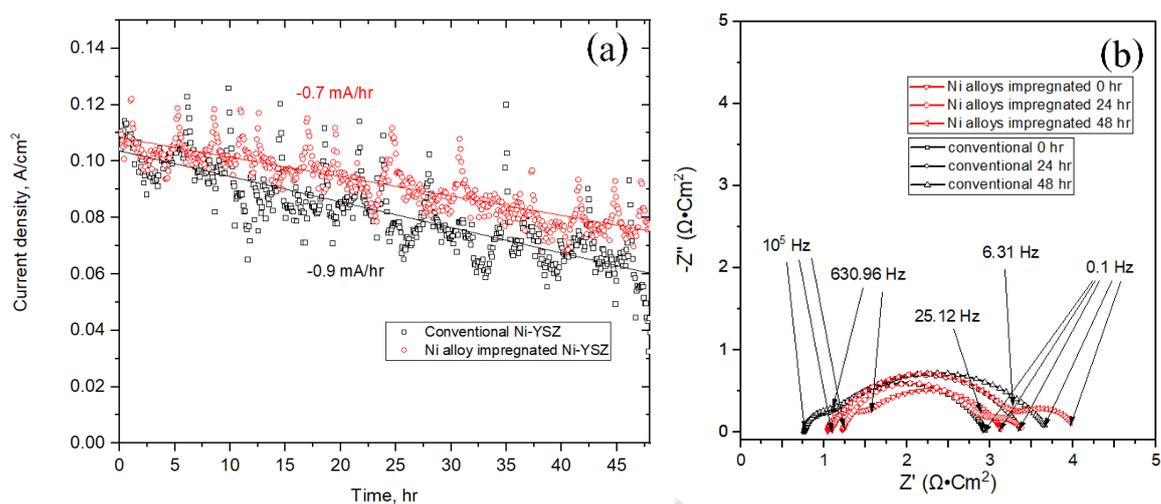

Fig. 40 Comparison of Ni alloy impregnated Ni-YSZ/YSZ/BSCF and conventional Ni-YSZ/YSZ/BSCF (a) the durability at applied 1.1 V and (b) electrochemical impedance response at different duration (800 °C and  $H_2O:H_2 = 70:30$ )

Table 16 Resistance of the Ni-YSZ/YSZ/BSCF and Ni alloys impregnated Ni-YSZ/YSZ/BSCF.  $R_0$ ,  $R_{HF}$  and  $R_{LF}$  are referred to ohmic resistance and polarization resistance in high frequency region and low frequency region, respectively.

| Duration (hr) | conventional Ni-YSZ/YSZ/BSCF         |   |   |  | Ni-alloy impregnated Ni-YSZ/YSZ/BSCF |   |   |  |

## Chapter V

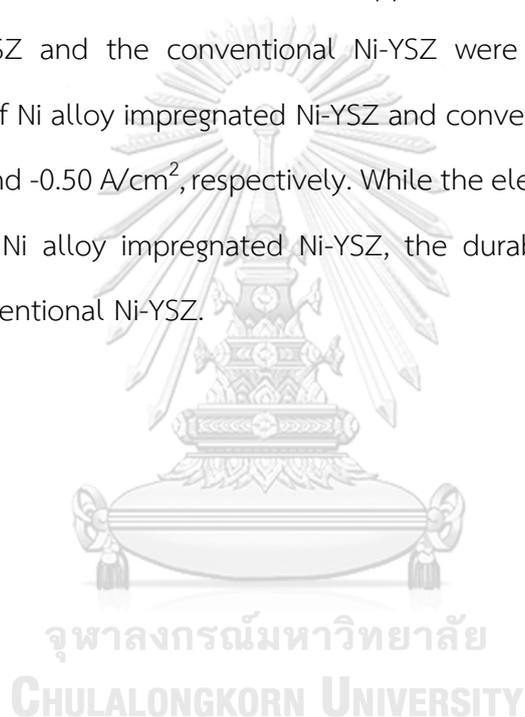

### Conclusion

Ni alloy containing Cr and Fe were introduced to improve the oxidation resistance of the conventional Ni-YSZ hydrogen electrode in solid oxide electrolysis cell. Oxidation tolerance, binding energy, crystallite size, reduction temperature, powder and electrode morphology were investigated. Electrochemical performance was measured. Increasing Fe content in the cathode improved the oxidation tolerance. However, the effect of Cr content shows unusual behavior in oxidation prevention and the similar trends of degree of oxidation with the conventional Ni-YSZ with Alloy 600-YSZ may cause by the difference surface area of the samples. The Alloy 600-YSZ begins to oxidize at 600 °C while conventional Ni-YSZ begins at 300 °C. The Cr<sup>6+</sup> Cr<sup>3+</sup> and Fe<sup>3+</sup> were specified. The negative shifts of binding energy were referring to the lower electronegativity of the chromium and iron. The crystallite size and the alloy formation were investigated by XRD analysis. A small peak of NiCr<sub>2</sub>O<sub>4</sub> and NiFe<sub>2</sub>O<sub>4</sub> were detected. The addition of Alloys loading reduced the crystallite size compared to conventional Ni-YSZ.

The reducibility of NiCr-YSZ and NiFe-YSZ electrode were investigated. For NiCr-YSZ, only one TPR reduction peak was observed at around 500 to 700 °C. The negative peak shift was seen when increasing Cr contents, implying increasing reducibility. High Fe loading increased the reduction temperature. Various compositions of alloy content were used to fabricate the cathode-supported cell. Although densification of the cathode increased with increasing Cr, fabricated cathodes from alloys-YSZ were fragile and brittle. To measurement the performance of each composition, the electrolyte-

supported cell was then fabricated instead of the cathode support. NiFe-YSZ layer peeled off after sintering due to thermal expansion.

Electrochemical performance of electrolyte-support NiCr-YSZ/YSZ/Pt was investigated. The cell with the cathode with 5% Cr loading shows the highest current density at 800 °C compared to the other compositions. The current density was  $-1.09 \text{ A/cm}^2$  at operating voltage of 1.8 V using steam to hydrogen ratio of 70:30. The electrochemical performance of cathode-supported cells having the Ni alloy impregnated Ni-YSZ and the conventional Ni-YSZ were investigated. The highest current densities of Ni alloy impregnated Ni-YSZ and conventional Ni-YSZ at 1.8 V and 800 °C was  $-0.26$  and  $-0.50 \text{ A/cm}^2$ , respectively. While the electrochemical performance decreased in the Ni alloy impregnated Ni-YSZ, the durability was improved when compared to conventional Ni-YSZ.

## Appendix A

### A.1 Material

Table A.1 Materials

| No. | Material name   | Company       |
|-----|---|---------------|
| 1   | Nickle oxide powder   | Kceracell     |
| 2   | Ni-Cr powder  | Kceracell     |
| 3   | Ni-Fe powder  | Kceracell     |
| 4   | LSM-YSZ ( $\text{La}_{0.80}\text{Sr}_{0.20}\text{Mn}_{1.02}\text{O}_3\text{-(Y}_2\text{O}_3\text{)}_{0.08}\text{(ZrO}_2\text{)}_{0.92}$ ) | Kceracell     |
| 5   | BSCF ( $\text{Ba}_{0.5}\text{Sr}_{0.5}\text{Co}_{0.8}\text{Fe}_{0.2}\text{O}_{3-\delta}$ )  | Kceracell     |
| 6   | 8% Yttria stabilized zirconia powder  | Sigma-Aldrich |
| 7   | Polyvinyl butyral resin (Butvar98)  | Chemcruz      |
| 8   | Polyethylene glycol (PEG)   | Sigma-Aldrich |
| 9   | Polyvinylpyrrolidone (PVPD)   | Sigma-Aldrich |
| 10  | Alpha terpineol (Binder)  | Sigma-Aldrich |
| 11  | Butyraldehyde   | Sigma-Aldrich |
| 12  | Xylene  | Sigma-Aldrich |
| 13  | Ethanol   | Sigma-Aldrich |

### A.2 Porosity

The porosity of each hydrogen electrode was measured by ImageJ program. Porosity is decreased with the increasing of Cr content, as seen in Table A.2.

Table A.2 porosity (%) of various Ni-Cr-YSZ electrode

| Composition     | porosity (%) |
|-----------------|--------------|
| 55 Ni 5 Cr YSZ  | 32.37        |
| 50 Ni 10 Cr YSZ | 8.47         |
| 45 Ni 15 Cr YSZ | 2.27         |
| 40 Ni 20 Cr YSZ | 6.95         |

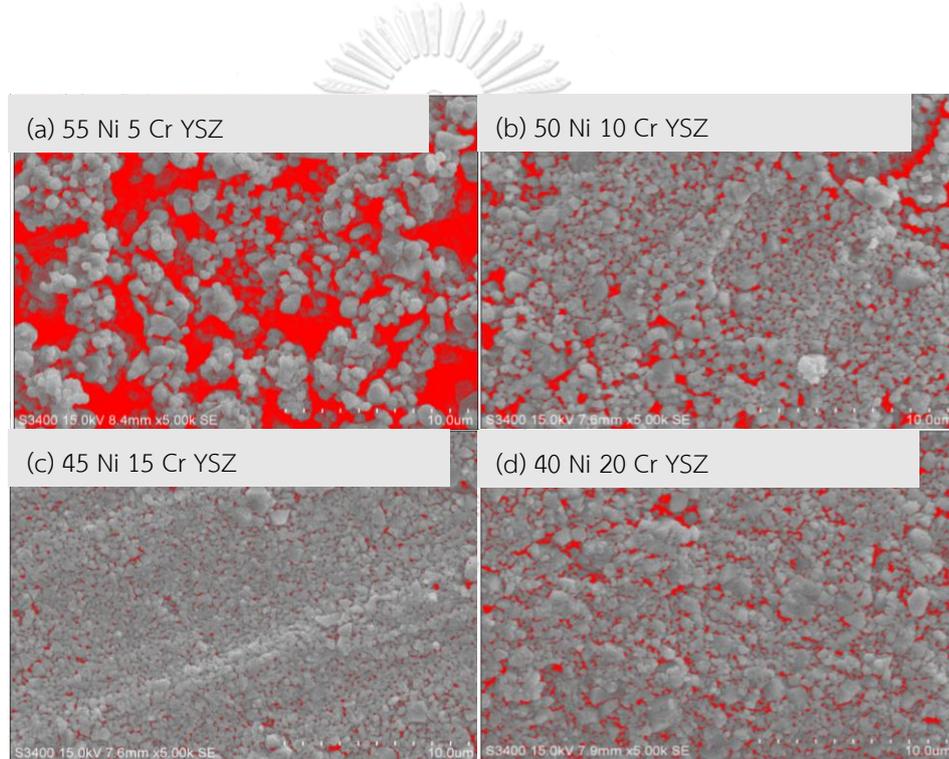

Fig. A.1 the analyzed SEM image of a) 55 Ni 5 Cr YSZ b) 50 Ni 10 Cr YSZ c) 45 Ni 15 Cr YSZ and d) 40 Ni 20 Cr YSZ electrode using the ImageJ program.

The porosity of conventional of Ni-YSZ, Alloy wash-coated Ni-YSZ and Alloys impregnated Ni-YSZ is shown in Fig. A.3.

Table A.3 porosity (%) of conventional Ni-YSZ, Alloys wash-coated Ni YSZ and Alloys impregnated Ni-YSZ

| Composition               | porosity (%) |
|---------------------------|--------------|
| Conventional Ni-YSZ       | 23.91        |
| Alloys impregnated Ni YSZ | 19.72        |
| Alloys wash-coated Ni-YSZ | 8.96         |

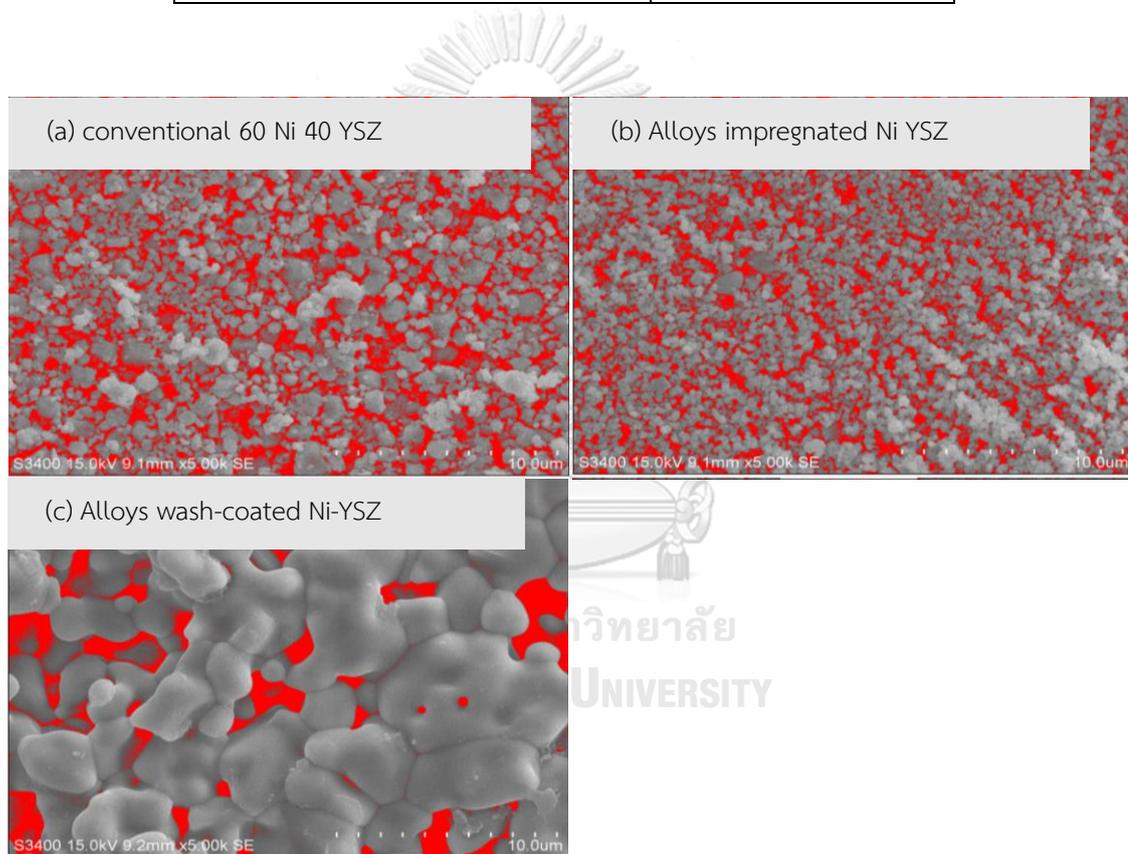

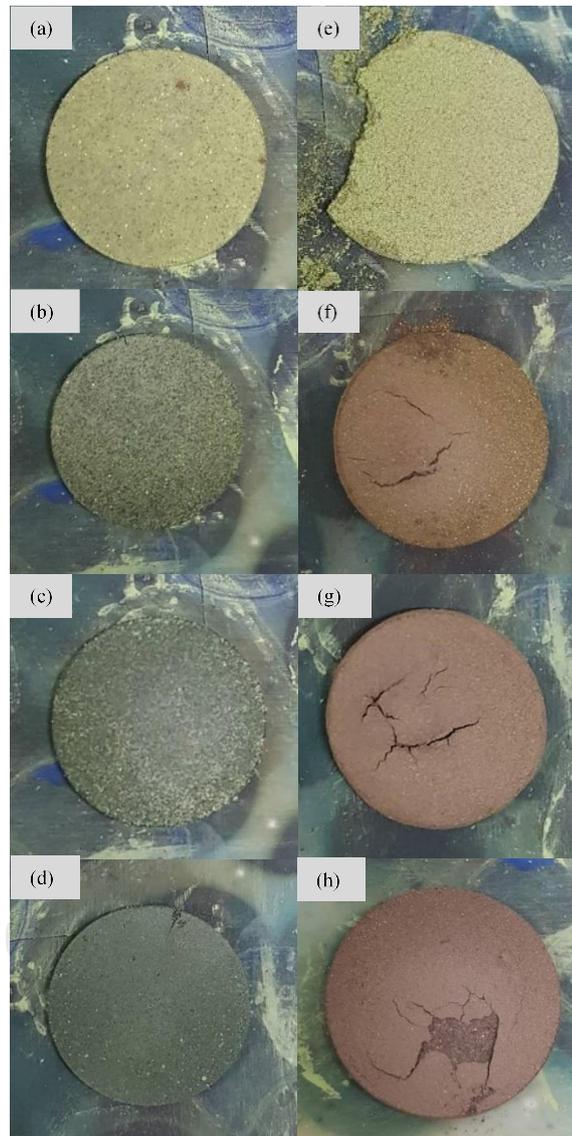

Fig. A.2 the analyzed SEM image of a) conventional Ni-YSZ b) Alloys impregnated Ni-YSZ c) and Alloys wash-coated Ni-YSZ electrode using the ImageJ program.

A.3 Scanning electron microscope and energy Dispersive X-ray Spectrometer  
(SEM-EDX)

Fig. A.15 The SEM patterns at 800X magnification of cross sectional sintered (a) conventional Ni-YSZ (b) 55Ni 5Cr-YSZ (c) 50Ni 10Cr-YSZ (d) 45Ni 15Cr-YSZ and (e) 40Ni 20Cr-YSZ electrode using electrolyte as a support at 1100 °C for 2 hr

#### A.4 Calculation of hydrogen production rate

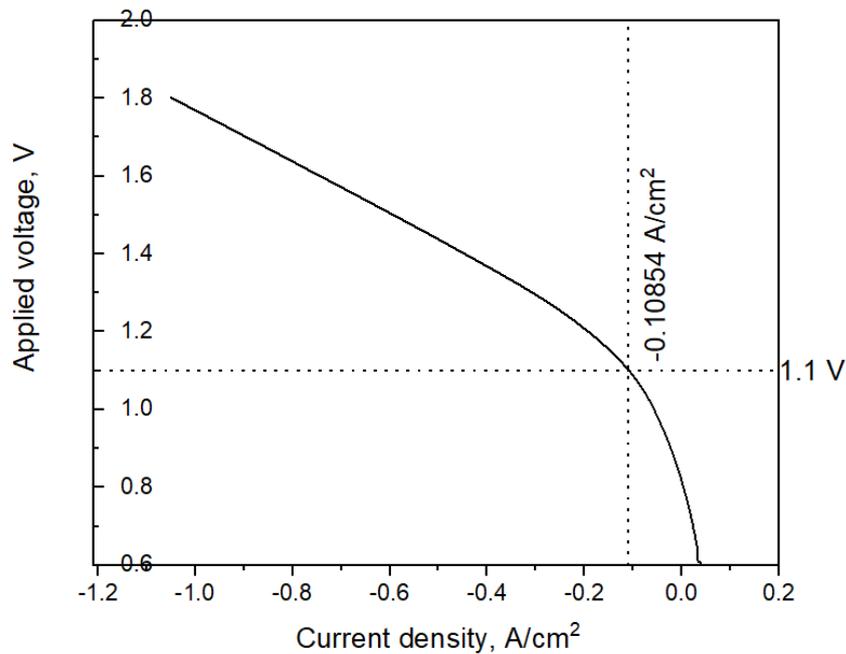

Fig. A.16 IV profile of electrolyte supported 55Ni 5Cr 40 YSZ/YSZ/Pt at 800 °C using steam to H<sub>2</sub> ratio at 70:30

จุฬาลงกรณ์มหาวิทยาลัย  
CHULALONGKORN UNIVERSITY

$$m = \frac{I}{nF}$$

... (A.1)

Where

m is an amount of mole is generated per area, I is a current (A or Coulomb/s),  
n is an amount of electron is generated in reaction (in this reaction n = 2 ),  
and F is the Faraday's constant (96,485 C/mol)

At 1.1 V, current density was 0.1085 A/cm<sup>2</sup>. So, hydrogen production rate was

$$\frac{0.1085}{2 \times 96,485} = 5.62 \times 10^{-7} \text{ mol s}^{-1}$$

A.5 Calculation of open circuit voltage (OCV)

$$E = E^0 - \frac{RT \ln \left( \frac{p_{\text{H}_2\text{O}}}{p_{\text{H}_2} \sqrt{p_{\text{O}_2}}} \right)}{nF} \quad \dots (\text{A. 2})$$

$$E^0 = -\frac{\Delta G^0}{nF} \quad \dots (\text{A. 3})$$

when E is the cell potential at the interested temperature, E<sup>0</sup> is the standard cell potential, R is the universal gas constant (8.314 JK<sup>-1</sup>mol<sup>-1</sup>), T is the temperature in kelvins, n is the number of electron transferred (in this reaction n = 2), F is Faraday constant (96,485 C mol<sup>-1</sup>) and ΔG<sup>0</sup> is a standard Gibbs free energy.

At 900 °C using steam to hydrogen ratio of 70:30

For 150 ml/min total flow, 20 ml/min of H<sub>2</sub> and 46.67 ml/min of H<sub>2</sub>O were fed and 83.33 ml/min of N<sub>2</sub> was used to balance the flow.

ΔG<sup>0</sup> for the H<sub>2</sub> + ½ O<sub>2</sub> → H<sub>2</sub>O reaction at 900 °C is -183.18 KJ/mol

Therefore,  $E^0 = \frac{183,180}{2(96485)} = 0.9493 \text{ V}$

$$E = 0.9493 - \frac{8.314(1173.15) \ln \left( \frac{46.67/150}{(20/150)\sqrt{0.21}} \right)}{2(96,485)}$$

$$= 0.87 \text{ V}$$

A.6 Calculation of crystallite size by Sherer equation

$$B(2\theta) = \frac{K\lambda}{L \cdot \cos\theta} \quad \dots (A. 4)$$

Where L is crystallite dimension, B is the full width at half maximum intensity,  $\theta$  is the Bragg angle, K is a Scherrer constant (0.94) and  $\lambda$  = X ray wavelength (1.54)

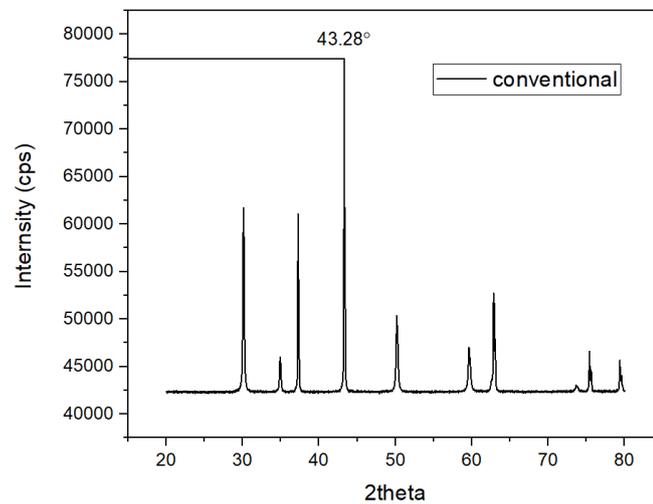

Fig. A.17 XRD pattern of conventional Ni-YSZ

The half intensity is 38,750 cps. FWHM is 0.2066.

$$B = \frac{\text{FWHM} \times 2\pi}{360} \quad \dots (\text{A.5})$$

$$B = \frac{0.2066 \times 2\pi}{360} = 0.0036$$

$$\text{From eq (A.4)} \quad L = \frac{K\lambda}{B(2\theta) \cdot \text{Cos}\theta} = \frac{0.94(1.54)}{0.0036 \cdot \text{Cos}(21.54)}$$

$$= 433.9 \text{ \AA} = 43.39 \text{ nm}$$
