ABSTRACT: The acid-catalyzed models on reaction mechanisms of pinacol rearrangement of propylene glycol conversion to propanal and propanone have been investigated using density functional method at 298.15 K. Thermodynamic quantities of activation steps of four water-addition models were obtained. The number of added water interacting with the transition states of three concerted pathways has obviously affected the product ratio. The relative energetic profiles of the conversion reactions of all solvation models have been comparatively displayed. Estimation of percent ratio of product composition computed from activation free energies of each acid-catalyzed reaction models were carried out. The percent ratios of propanal and propanone were decreased as the number of added water increased.

Key words: density functional theory; acid-catalyzed models; propylene glycol; propanal; propanone; rate constant

Introduction

The pinacol rearrangement in the conversion of glycol to propanal was reviewed by Wheland.¹ The pinacol rearrangement has been described to proceed only with a stepwise mechanism via carbocation intermediate which was first introduced by Whitmore.² The reaction mechanism and migratory aptitude of the pinacol rearrangement were theoretically examined for protonated 1,2-ethanediols using RHF/6-31G method.³ The rearrangements of many reactions were found where they have involved not only the stepwise but also the concerted mechanism.³⁻⁶ Smith and

RHF/6-31G method.³ The rearrangements of many reactions were found where they have involved not only the stepwise but also the concerted mechanism.³⁻⁶ Smith and coworker⁷ applied the E2 process of dehydration mechanism in the elimination reactions of 2-bromobutane in water. Two possible mechanisms of ethylene glycol conversion to acetaldehyde were proposed by Smith⁸ using the theoretical approaches. The dehydration mechanism were energetically compared to the pinacol rearrangement of concerted mechanism and the latter process was shown proceed at a lower activation enthalpy than the dehydration mechanism by 69.8 kcal mol⁻¹.⁸ Recently, the dehydration of ethylene glycol in near-critical water with the zinc chloride catalyst to obtain hydrolysis product 2-methyl-2-pentenal has been carried out.⁹ Nevertheless, several reports supported that the pinacol rearrangement does not proceed by the stepwise mechanism^{10,11} and in the gas phase the stepwise mechanism being less favored than the concerted mechanism has been found.¹²⁻¹⁴ In present work, the pinacol rearrangement of propylene glycol conversion to propanal and propanone at various acid-catalyzed models has been therefore theoretically investigated via the concerted mechanism by density functional method. The concerted mechanism of the system respectively including one-, two- and three-waters clusters defined as models II, III and IV have been investigated in order to observe their reaction products. The product composition of various acid-catalyzed models has been evaluated in order to get more understanding of the effect of the added water on the reaction products.

Computational method

Full geometry optimizations of entities were computed by density functional theory (DFT). Density functional calculations have been performed with the Becke's three parameters hybrid density functional using the Lee, Yang and Parr correlation functional (B3LYP).^{15,16} All geometry optimizations have been carried out using the hybrid density functional B3LYP with the 6-31G(d) basis set. The energies of the B3LYP/6-31G(d) optimized geometries have been calculated with the zero-point energy corrections. The B3LYP/6-31G(d,p) and B3LYP/6-311G(d,p) levels of theory were employed for the single point calculations of the B3LYP/6-31G(d) optimized geometries of involved species. The transition states have been located using the

frequency. The intrinsic reaction coordinate (IRC) method¹⁸ was used to track minimum energy paths from transition structures to the corresponding minimum. All calculations were performed with the Gaussian 03 program.¹⁹ The MOLDEN 4.2 program²⁰ was utilized to display molecular structures and observe the geometry convergence via the Gaussian output files. The molecular graphics of all species were generated with the MOLEKEL 4.3 program.²¹

The standard enthalpy ΔH^O and Gibbs free energy changes ΔG^O of conversion reactions of this system have been derived from the frequency calculations at B3LYP/6-31G(d) level of theory. The rate constant $k(T)$ derived from transition state theory was computed from activation free energy, $\Delta^\ddagger G^O$ by using $k(T) = \frac{k_B T}{hc^o} \exp(-\Delta^\ddagger G^O/RT)$ where concentration factor, c^o of unity is used, k_B is Boltzmann's constant, h is Plank's constant, T is the absolute temperature and R is gas constant.²² The above formula was employed to compute the reaction rate constants for corresponding activation free energies as introduced in previous works.²³⁻²⁴

The multi-transition-state system introduced by Adam²⁵ was extended for the Curtin-Hammett principle²⁶ which is the two competitive transition states. As the present work is a tri-transition-state system without pre-reaction cluster, the reaction scheme of this system is therefore reduced as shown in Figure 1. According to transition state theory, the rate constant for each individual reaction i is given by equation 1.²⁷

$$k_i(T) = \frac{k_B T}{hc^o} \exp(-\Delta^\ddagger G_i^O/RT) \quad (1)$$

Where $\Delta^\ddagger G_i^O = G_i^{TS,O} - G_o^O$, i is the rank of reaction paths ($i = 1, 2$ and 3) and $G_i^{TS,O}$ and G_o^O are Gibbs free energies of transition state and corresponding reactant, respectively. As transition states TS1 and TS2 step forward to protonated form of propanal product (HPPNL⁺) and TS3 to protonated form of propanone product (HPPNE⁺), the product ratio of [HPPNL⁺] to [HPPNE⁺] is therefore equivalent to the ratio of the sums of all ground-state population of reactants P_o and its corresponding rate constants forward to product [HPPNL⁺] to sums for [HPPNE⁺]. Therefore, the [HPPNL⁺] to [HPPNE⁺] ratio can be given by equation 2.

$$\begin{aligned}
 \frac{[\text{HPPNL}^+]}{[\text{HDPNE}^+]} &= \frac{P_o k_1 + P_o k_2}{P_o k_3} = \frac{k_1 + k_2}{k_3} \\
 &= \frac{\sum_{i=1}^2 \exp(-\Delta^\ddagger G_i^0/RT)}{\exp(-\Delta^\ddagger G_3^0/RT)} = \frac{\exp(-\Delta^\ddagger G_1^0/RT) + \exp(-\Delta^\ddagger G_2^0/RT)}{\exp(-\Delta^\ddagger G_3^0/RT)} \quad (2)
 \end{aligned}$$

Where k_1 , k_2 and k_3 are forward rate constants of reaction pathways 1, 2 and 3, respectively as shown in Figure 1. In present work, four acid-catalyzed models with respect to the increased numbers of added water were investigated for the effect of added water to product compositions. Model I is an acid-catalyzed model of a gas-phase system which is composed of one proton as acid catalytic atom without solvation water except a dehydration water which is released from the reaction. Model II is an acid-catalyzed model of which the reactant is protonated by a single proton of which the molecule is hydrated by one water molecule. Models III and IV are acid-catalyzed models of which protonated species are hydrated by one and two water molecules, respectively.

Results and discussion

All structures were optimized using DFT at B3LYP/6-31G(d) level of theory. The zero point energies and thermodynamic quantities of activation steps were derived from the frequency calculations at 298.15 K at the same level of theory. Reaction mechanisms of propylene glycol (PG) conversion to propanal (PPNL) and propanone (PPNE) of various acid-catalyzed water-addition models of three concerted pathways were found. This conversion reaction has been investigated using the protonated forms of propylene glycol (HPG^+), propanal (HPPNL^+) and propanone (HPPNE^+). A representative scheme of a concerted reaction mechanism of propylene glycol conversion to propanal and propanone via transition states TS1, TS2 and TS3 which are the secondary and primary carbonium ions is shown in Figure 2. Total energies and geometrical structures of species HPG^+ , HPPNL^+ and HPPNE^+ and the corresponding transition states of various acid-catalyzed models were determined at the B3LYP/6-31G(d) level of theory with zero point energy corrections. The

corresponding transition states of various acid-catalyzed models were determined at the B3LYP/6-31G(d) level of theory with zero point energy corrections. The activation thermodynamic quantities, forward and backward rate constants of acid-catalyzed reaction models I, II, III and IV are shown in Table 1, 2, 3 and 4, respectively. The three concerted pathways (1) C1H, (2) C1Me and (3) C2H via transition states TS1 and TS2, and TS3 have afforded the products HPPNL⁺ and HPPNE⁺, respectively. Figure 1 shows that the product HPPNL⁺ was produced via transition states TS1 and TS2 and HPPNE⁺ via transition state TS3. The magnitude orders of forward rate constants of four reaction models as tabulated in Table 1, 2, 3 and 4 are concluded as

The typical structures of transition states TS1, TS2 and TS3 are the secondary (C2H), primary (C1Me) and primary (C1H) carbonium cations, respectively. As the decreasing order of structural stability of carbonium ions is as tertiary > secondary > primary, the secondary carbonium ion of transition state TS1 (C2H) is the stable species in gas-phase which is much more stable than the transition states TS2 and TS3 in gas-phase which is defined as model I. As the primary carbonium ions of transition states TS2(C1Me) and TS3(C1H) are stabilized in aqueous-phase which is defined as model IV, the tri-solvation of TS3(C1H) was found to be more stable than its mono-solvation in model I. The stability order of transition state TS3 with respect to TS1 and TS2 is remarkably changed at high number of solvation water of model IV as shown in following scheme,

B3LYP/6-31G(d)//B3LYP/6-31G(d), B3LYP/6-31G(d,p)//B3LYP/6-31G(d) and B3LYP/6-311G(d)//B3LYP/6-31G(d) levels of theory are tabulated in Table 5. Table 5 shows that the activation energies derived from the total energies of transition states TS1, TS2 and TS3 using single point calculations are in the same order of magnitudes with respect to the B3LYP/6-31G(d) energies of zero-point energy corrections. The reactant HPG⁺, transition states TS1, TS2 and TS3 and products HPPNL⁺ and HPPNE⁺ in model I, II, III, IV and V are shown in Figures 4, 5, 6 and 7, respectively. The O...H distance of hydrogen bond of intermolecular interaction between water molecule(s) and involved species and their dipole moments are shown in Figures 4, 5, 6 and 7. The percent compositions of products HPPNL⁺ and HPPNE⁺ derived from equation 2 are tabulated in Table 6. The models I, II and III in Table 6 result that the HPPNL⁺ is the dominant product of which percent are larger than 85 %. For the product ratio of HPPNL⁺ to HPPNE⁺ of the model IV is 46.59 to 53.41. However, the experimental values of the ratio HPPNL⁺ to HPPNE⁺ in acidic aqueous solution have been not found but the amino alcohol CH₃CC₆H₅C(OH)CH₂NH₂ conversion reaction, the distribution ratio (in %) of products C₆H₅CH₂CHOCH₃ (benzyl methyl ketone) is 75 to 25.²⁸

Conclusions

The zero point energies and thermodynamic quantities of activation steps were obtained at B3LYP/6-31G(d) level of theory. Reaction mechanisms of propylene glycol (PG) conversion to propanal (PPNL) and propanone (PPNE) of various acid-catalyzed water-addition models of three concerted pathways were investigated using the protonated forms of propylene glycol (HPG⁺), propanal (HPPNL⁺) and propanone (HPPNE⁺). The three concerted pathways C2H, C1Me and C1H via transition states TS1 and TS2, and TS3 have produced the products HPPNL⁺ and HPPNE⁺, respectively. The percent ratios of product HPPNL⁺ to HPPNE⁺ based on models I, II III and IV are [99.88]:[0.12], [99.81]:[0.19], [89.01]:[10.99] and [46.59]:[53.41], respectively.
