A set of 32 antimalarial tricyclic 1,2,4-trioxane compounds was subjected to classical QSAR, 3D-QSAR(CoMFA) and molecular docking studied. All compounds were geometry optimized with ab-initio method at the HF/3-21G level. The activities measured against NF54 strain of malarial parasites were used. The models obtained from classical QSAR and 3D-QSAR(CoMFA) techniques are satisfied based on both statistical significance and predictive ability. For docking studies, The atomic charges of these compounds were obtained from single point calculations using 6-31G(d) basis set and the atomic charges of heme were calculated at $6-311 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level. The results derived from the structure-based design using molecular docking study reveal that $\mathrm{Fe}^{2+}$ approaches tricyclic 1,2,4-trioxane compounds at the $\mathrm{O}_{1}$ or $\mathrm{O}_{2}$ atoms depending on the substituted position of the compound. These results suggested similar mechanism of action to that of artemisinin. All results can support each other and can be used as a guideline to design and predict the new compounds with increasing malarial inhibitory activities.

## ACKNOWLEDGEMENT

This thesis would not have been accomplished without contributions from many persons who helped me to overcome extensive hindrances and difficulties during my past 3 years of study. Truely, I cannot acknowledge the names of all individuals who either directly or indirectly give me a help, and would like to apologize to them whom I fail to mention.

I wish to express my deepest appreciation and grateful thank to my thesis advisor, Associate Professor Dr. Sirirat Kokpol for her concern, encouragement and valuable advice throughout my period of study.

I would like to express my grateful thank to my co-advisor, Associate Professor Dr. Vudhichai Parasuk for generously guiding, kindly helping and encouraging throughout the course of this thesis.

I also would like to thank the thesis committee, Associate Professor Dr. Siri Varothai, Assistant Professor Dr. Pornthep Sompornpisut, Dr. Pongchai Harnyuttanakorn for their kind attention, valuable construction, criticism and helpful suggestions.

I also would like to thank the National Electronics and Computer Technology Center (NECTEC), Thailand, the Austrian-Thai Center for Computer Assisted Chemical Education and Research (ATC) and Compuatational Chemistry Chemical Unit Cell, Chulalongkorn University, Thailand for computer resources and other facilities. Gratefully thanks to Professor Dr. Karl Peter Wolschann for computer program TSAR software.

My sincere gratitude and deep appreciation are expressed to Associate Professor Dr. Supot Hannongbua and Dr. Tawun Remsungnen.

My work would not have been succeeded without the kindness of Dr. Somsak Tonmunphean.

I wish to express my infinite gratitude to my family and my friends for their everlasting love, understanding and encouragemnt.

Finally, I gratefully acknowledge the financial supports from the Graduate School, Chulalongkorn University and the Ratchdaphisek Somphot Endowment grant (CE scholarship).

## CHAPTER 1

## INTRODUCTION

Drug discovery and development has long been the largest research area in life science. Drug research apparently plays an important role in improving quality of human health. Modern drugs are highly effective form of treatment. They are developed from organized research system discover precise treatment for diseases. The discovery of pharmaceutical agent has gone through an evaluation over the years and new technologies has been adding to this increasing complex process.

A modern approach to drug discovery deals with knowledge of biochemical pathway involving the diseases and mechanism of drug actions. It is important to know about the detail structural properties of drug molecules. Many drugs are substrate-like molecule since they hit precisely to specific target enzyme. Thus, knowledge of three dimensional structures contains useful information in designing new drugs. Rational drug designs are nowadays carried out by computer programs. This computational approach is generally known as Computer Aided Drug Design (CADD).

Quantitative Structure Activity Relationship (QSAR), one of CADD techniques, has been used for decades. QSAR constructs a mathematical expression derived from statistical relationship between chemical structure and biological activities of a series of compounds. Then, the model can be used to make an initial guess of biological activity before synthesizing the compounds. Moreover, the model obtained from QSAR method gives information on how to modify chemical property to increase the biological activity. Another technique of CADD is molecular docking which is used to predict possible interactions between drug and receptor. The knowledge obtained from the docking could be used for accurately structural modifications of drug to enhance the interactions.

In the CADD, quantum mechanical methods are increasingly used to calculate molecular and electronic properties due to some advantages over the experimental works. There are two main advantages. Firstly, they are cheaper and more convenient while give very reliable values as compared to those of experiments. It is, therefore, reduce number of synthesized compounds. Furthermore, the power in terms of hardware and software is increasing while the cost of computing is steadily
decreasing. Secondly, they are able to calculate some properties that are very difficult or impossible to measure experimentally, such as electronic properties. Moreover, from these methods, it is possible to derive properties that depend upon the electronic distribution and in particular to investigate chemical reactions in which bonds are being broken and formed.

In this thesis, ligand-based drug design approaches using classical QSAR and 3D-QSAR as well as structure-based drug design procedures using molecular docking were applied to antimalarial 1,2,4-trioxane compounds.

### 1.1 Life Cycle of Malaria parasite

Malaria is transmitted to human by a bite of an infected female anophele mosquitoe. The parasite first invades and develops within hepatocytes, and then colonizes in erythrocytes where it achieves asexual multiplications (Figure 1.1). Within erythrocytes, Plasmodium digests main part of host hemoglobin (20-80\%) and use released amino-acids to build its own proteins. The synchronous intraerythrocytic maturation of parasites leads to cell burst going together with fever access and deep anemia. At each red blood cell burst (each 48 hours for P. falciparum), non mature parasites called merozoites are released for further erythrocytic reinvasion, and also gametocytes that will achieve a sexual development of the parasite within mosquito after reabsorption by biting an infected man.

Figure 1.1 Plasmodium falciparum life cycle within human. ${ }^{1}$

### 1.2 Situation of malaria in the World and in Thailand

### 1.2.1 Malaria in the World

Malaria is one of the leading causes of morbidity and mortality in tropical and subtropical regions. The disease causes about 1.22 million deaths per year according to the World Health Organization 2003 report., ${ }^{2}$ which is a low estimate. In fact, obtaining accurate information on the rate of mortality and morbidity is not easy, since symptoms of acute malaria are similar to those of many other acute infectious diseases, and facilities for investigation of suspect cases are not available, leading to an under estimation of malarial cases. Four Plasmodium species are responsible for malaria in human. P. malariae and P. ovale are universally susceptible to the cheap and well tolerated drug chloroquine. $P$. vivax is widely extended and some cases of resistance appeared, however it is not lethal. P. falciparum is responsible for all the malignant cases. Severe malaria (cerebral malaria) is an encephalopathy that, even with a suitable treatment, can lead to death in 2-3 days (10-30\% of cases). This latter species is also involved in all main cases of drug resistant malaria. ${ }^{3}$

The control of malaria nowadays largely depends on drug therapies. Several classes of drugs can be considered according to the target parasite stage. Schizontocides are able to inhibit the proliferation of schizonts within red blood cells. Among them, quinine is still a powerful drug. This 4-quinoline-methanol has been used as a lead structure for the design of synthetic antimalarial agents, between chloroquine and mefloquine are well known. Gametocytocides are active against sexual stages of the parasite. Few 8 -aminoquinolines exhibit this kind of reactivity and in this class, primaquine was found to be efficient, including against intrahepatic stages.

During the World War II to the 1980s, a wide use of chloroquine for prophylaxis, associated with a fight against mosquitoes by draining wet lands and using insecticides such as DDT, let to a reduction of malaria in endemic areas. In the 1950s, the WHO optimistically targeted malaria for eradication. The United States and Europe got clear of malaria in the 1960s. The first case of resistance to chloroquine was reported in 1959 in South America, followed quickly by a report from South-East Asia. Since then, resistance has spread throughout those areas where P. falciparum is endemic. Unfortunately, a rapid development of an anophele resistant to pesticides that have been widely used (for instance soaked bed nets, resulting in
some areas in a substantial reduction of child mortality) and the resistance of $P$. falciparum to main classes of drugs (chloroquine is no longer useful in most of the endemic areas) have quickly made the eradication out of sight. Furthermore, drugresistant malaria is rapidly spreading and many regions that are now suitable might become contaminated in the next decades.

Although falciparum malaria is of course a public health scourge in endemic areas, northern countries, including large parts of Europe and the United States, might not be out of concern due to possible climate variations and increasing travels in endemic regions.

### 1.2.2 Malaria in Thailand

In Thailand, malaria is found mostly in the Thai-Cambodian border and the western border of Thailand with Myanmar and approximately 100,000 people are infected and around 800 people die from the disease annually. ${ }^{4}$ Malaria in Thailand was first documented during the reign of King Narai the Great of Ayutthaya (B.E. 2203-2230). ${ }^{5}$ Today malaria still remains an important health problem in Thailand. On the Thai-Myanmar border there is a very high level of drug resistence, with evidences both in vitro and in vivo for P. falciparum parasites that are highly resistant to chloroquine, sulfadoxine-pyrimethamine and mefloquine and to a lesser extent to quinine. Antimalarial drug resistance has spread and intensified over the past 40 years leading to a dramatic decline in the efficacy of the most affordable antimalarial drugs (Table 1.1).

Table 1.1 Antimalarial drugs exploited since 1930.

| Old drugs $19 \sim 9 /$ | $191 \sim \cap$ New drugs |
| :---: | :---: |
| - Cinchona alkaloids, pamaquine <br> - Mepacrine, chloroquine <br> - Proguanil, amodiaquine <br> - Pyrimethamine, primaquine <br> - Pyrimethamine-sulfa combinations | - Artemisinin <br> - Artesunate, artemether, arteether <br> - Pyronaridine <br> - Mefloquine, halofantrine <br> - Atovaquone-proguanil <br> - Artemether-lumefantrine <br> - Tafenoquine |

New antimalarial drugs have been investigated in recent years in Thailand. Atovaquone, a hydroxynaphthoquine, was evaluated and the compound alone was
proved to be safe and effective. All patients treated had clinical cure, however, one third of the patients had late recrudescence (RI). When atovaquone was combined with proguanil, the cure rate increased to $100 \%$. ${ }^{6,7}$ This combination has been developed as a fixed combination drug (Malarone®). Artemisinin derivatives such as artesunate, artemether, arteether and dihydroartemisinin were also tested. Arteether, a WHO/TDR supported drug, has been evaluated in a hospital and was recently has been licensed as Artemotil® for the use in severe malaria. ${ }^{8}$ Other combinations (artemisinin derivatives combined with lumefantrine or doxycycline and mefloquine combined with tetracycline or doxycycline) have also been evaluated with improvement of cure rates. ${ }^{9,10}$ Recently, a fixed combination of artemether and lumefantrine (Coartem ${ }^{\circledR}$ ) has proven to be a safe and effective drug for the treatment of falciparum malaria. ${ }^{11,12}$ At present, studies with combinations of artemisinin derivatives plus mefloquine are being investigated. In general, artemisinin derivatives combined with mefloquine has been a standard regimen for the treatment of multidrug-resistant falciparum malaria in Thailand. Until proven otherwise, drug combinations are still remaining the recommended agents for treating patients suffering from acute uncomplicated falciparum malaria contracted in multidrugresistant areas.

### 1.3 Antimalarial drugs

### 1.3.1 Classification of Antimalarial Drugs

A classification of antimalarial drugs can be done in many ways depending on a criteria used, such as chemical structure, drug target, and drug action. However, a biological classification, based on parasite stage in which drug mediates its action, is widely used. ${ }^{13}$ According to this classification, 5 categories are defined as follows.
21.3.1.1 Primary Tissue Schizontocides (causal prophylaxis drugs). The drugs belonging to this class, e.g., proguanil and chloroquanide, exert a lethal effect on the pre-erythrocytic stages of parasite (primary tissue forms or primary exo-erythrocytic forms). Thus, they completely prevent an invasion of parasites to red blood cells and also a further transmission of malaria to mosquitoes.
1.3.1.2 Secondary Tissue Schizontocides (radically curative drugs). The drugs, e.g., primaquine, eradicate exoerythrocytic stages or tissue forms of $P$. vivax and $P$. ovale and thus able to achieve radical cure of these infections. Individuals living in
endemic areas are not suitable candidates for radically curative therapy due to the considerable likelihood of reinfection. Normally, the treatment is usually reserved for persons who experience relapsing vivax malaria after leaving malarious regions.
1.3.1.3 Schizontocides (blood schizontocides or schizontocidal drugs). The drugs act rapidly on erythrocytic stages (schizon) of parasites in red blood cells. By interrupting an asexual reproduction of malarial parasite, the clinical attack is terminated. Continuing use of schizontocides for a longer period than a life-span of the infection can completely eliminate malarial parasites from the body. Chloroquine, quinine, mefloquine, halofantrine, artemisinin, and antifolate compounds are belonging to this class.
1.3.1.4 Gametocytocides (gametocytocidal drugs). Agents in this category, e.g., primaquine, chloroquine, and quinine, destroy all sexual forms of malarial parasites in the human blood including those of P. falciparum. Thus, they eliminates the reservoir from which mosquitoes are reinfected. They also act on the development stages of malarial parasites in Anopheles, thus some of them form the next group of drugs.
1.3.1.5 Sporontocides (sporontocidal drugs or antisporogonic drugs). Drugs in this category, e.g., primaquine and pyrimethamine, prevent or inhibit the formation of oocysts and sporozoites in Anopheles. Therefore, they interfere with the transmission of malaria.

### 1.3.2 Antimalarial Therapy for Tomorrow

### 1.3.2.1 Drug Combination

It is now the WHO policy to develop a use of artemisinin derivatives as firstintention drugs to treat severe malaria. A combination of two antimalarial drugs should allow to improve a treatment efficacy and to avoid an emergence of resistant strains. If one parasite is resistant to a drug A in a population of $10^{9}$ parasites, and one parasite is resistant to a drug $B$ in a population of $10^{9}$ parasite, only one in a population of $10^{18}$ parasites will be resistant to both drugs A and B. Each ill person being carrier of $10^{8}$ to $10^{12}$ parasites so a probability of simultaneous resistance to two drugs acting with different modes is close to zero. ${ }^{14}$

Currenly, thr most widely used combinations are pyrimethamine + sulfadoxine, chloroquine + proguanil, and atovaquone + proguanil. However, these
combinations are poorly active against strongly chloroquine resistant strains. Artemisinin (or its derivatives) associated with mefloquine are currently used against multi-resistant strains of P. falciparum. ${ }^{15}$ Furthermore, it appeared that this combination is able to stop a progression of mefloquine resistance. ${ }^{16}$

### 1.3.2.2 Vaccines

A lot of efforts have been made for elaboration of malaria vaccines without success. ${ }^{17}$ None of the available in vitro assays are predictive of functional immunity in vivo, and there is no reliable animal model. Furthermore, the life cycle of Plasmodium is complex, several parasite stages in human are morphologically and antigenically distinct, and that obliges to conceive multivalent antigen vaccines. The near availability of a complete sequencing of the $P$. falciparum genome should improve the chances of existing of a vaccine. ${ }^{18}$ and will also allow the identification of new parasite proteins to be inhibited. But time is long from discovering targets to develop new therapeutic agents, and high costs are likely for this approach. ${ }^{19}$

### 1.3.2.3 Old Targets, New Compounds

An alternative strategy is an exploitation of known targets: recently discovered targets as the phospholipid (PL) metabolism of infected erythrocytes or old classical targets as the free heme in the food vacuole. The PL metabolism of infected erythrocytes is an effective pharmacological target because of its specificity: malaria parasite needs large amounts of phospholipids, mainly phosphatidylcholine (PC) to grow and divide. A supply of PC is achieved via a choline carrier. Quaternary ammonium and bis-ammoniums salts, designed as choline analogues to target this choline carrier, are highly active in vitro even against multi-resistant isolates. ${ }^{20}$ The free heme liberated in the parasite food vacuole is an "old" but always attractive pharmacological target: it is the most specific target that can be exploited since it comes from the hemoglobin digestion by the parasite, that occurs only in infected erythrocytes. Many chemical entities are directed toward this well-known target, among them are chloroquine and its derivatives, artemisinin and its derivatives. Many quinoline modifications have been investigated to obtain a molecule that is as affordable as chloroquine and active on resistant strains, e.g. by substitutions in the quinoline nucleus, variations in the side chain, ${ }^{21}$ synthesis of polyquinolines, ${ }^{22}$ and introduction of a ferrocenyl moiety. ${ }^{23}$ Such modifications seem to be enough to make
a compound that is active on resistant strains but the request for a safe and effective chloroquine alternative is still going on. Artemisinin and derivatives (artemether, arteether, artesunate) are more and more used in Asia and Africa where multidrug resistant P. falciparum is prevalent. But this series of molecules, as well as other antimalarial derivative, is based on artemisinin itself, a molecule having a very short life time in plasma. ${ }^{24}$ Furthermore, the artemisinin production is mainly limited to China and Vietnam, that is a handicap for other countries. An alternative is a development of synthetic trioxanes, simplified analogues of artemisinin retaining the crucial endoperoxide bridge, but up to now none of them has entered success fully in clinical trials. ${ }^{25}$

### 1.3.3 1,2,4-Trioxane Antimalrials

In the 1960s, chinese chemists began to screen traditional herbal drugs in order to find new antimalarial drugs. Among the herbs tested was Artemisia annua L., whose use dates back to 168 B.C. ${ }^{26}$ In 1972, chinese scientists reported seven sesquiterpene compounds. The compound with principal antimalarial properties was named qinghaosu (artemisinin). Several total syntheses of artemisinin have been reported since its isolation. Artemisinin (Figure 1.2) was found to act on blood phase of $P$. falciparum. Artemisinin and its derivatives are effective against both chloroquine sensitive and chloroquine resistant strains of $P$. falciparum. Artemisinin derivatives have also proven to be useful for a treatment of severe cerebral malaria. The downside of artemisinin based antimalarials is high recrudescence rates, which is attributed to a rapid metabolic clearance. Moreover, artemisinin is poorly soluble in both water and oil and is not well absorbed by a gastrointestinal tract. ${ }^{27}$

Figure 1.2 Stereochemistry and atomic numbering scheme of artemisinin.

Artemisinin and its hemisynthetic derivatives, artemether and artesunate, are highly efficient against multidrug-resistant parasite strains, but the cost of these naturally occurring drugs and the supply depending on contingencies are major drawbacks. The development of antimalarial synthetic trioxanes which are cheap and have a mode of action similar to that of artemisinin is essential.

The synthesis and testing of many simpler tricyclic trioxanes revealed that certain rings in artemisinin are redundant. Evidences from structure-activity relationship (SAR) investigations indicated the 1,2,4-trioxane as the critical pharmacophore and suggested that neither the peroxide function, nor the 1,2,4trioxane ring alone, are sufficient for maximum efficacy. ${ }^{28}$ However with the notation that ring A and lactone ring D (see Figure 1.2) are not essential ${ }^{29}$ for antimalarial activity. Moreover, several other active tricyclic 1, 2, 4-trioxanes have been synthesized, tested, and confirmed that the full tetracyclic array of artemisinin is not required for high activity. ${ }^{30,31,32}$

### 1.4 Aim of Our Study

Because the parasite's resistance to conventional drugs such as quinine, chloroquine, mefloquine and halofantraine is growing at an alarming rate, new efficient drugs are urgently needed. Therefore, more potent antimalarial drugs such as artemisinin, have been developed. Most of the antimalarial activity of artemisinin derivatives (but not artemisinin itself) is due to the metabolite dihydroartemisinin. Oral dihydroartemisinin treatment produces cure rates and parasite clearance time equivalent to historical controls treated with oral artesunate. Dihydroartemisinin can be manufactured more cheaply, however, it's pharmacokinetic and pharmocodynamic properties vary greatly and it has some major drawbacks such as poor solubility, short plasma half-life, and complex and expensive total synthesis process. Therefore, simplified analogous of artemisinin retaining the crucial endoperoxide bridge, tricyclic 1,2,4-trioxanes have been developed. Advantages of tricyclic 1,2,4-trioxane are: a) ease of synthesize, which makes the compounds cheap, and b) some of their derivatives are more potent than artemisinin. Most of publications on simple tricyclic 1,2,4-trioxanes deal with synthesis but only few publications on theoretical studies of tricyclic 1,2,4-trioxanes exist. ${ }^{33}$ Therefore, it is worth-while to explore antimalarial tricyclic 1,2,4-trioxanes compounds by some other techniques.

In this study, classical QSAR and 3D-QSAR (Comparative Molecular Field Analysis) were applied to 32 antimalarial tricyclic 1,2,4-trioxane compounds. Moreover, molecular docking calculations between tricyclic 1,2,4-trioxane compounds and heme were carried out to investigate their mechanism of action as well as to elucidate their intermolecular interactions. Relationships between biological activity and properties obtained from dock results such as binding energy, $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $\mathrm{O}_{2}$-Fe distance, and $\mathrm{O}_{13}$-Fe distance as well as other molecular properties were investigated. The obtained data are helpful for understanding the mechanism of action of tricyclic 1,2,4-trioxane compounds in more details which could aid in the development of new more effective antimalarial agents.

## CHAPTER 2

## THEORETICAL BACKGROUND IN QUANTUM CHEMISTRY

### 2.1 The Schrödinger Equation

The main goal of quantum chemical calculation is to compute energy and other properties of molecule. These properties can be obtained by solving the Schrödinger equation,

$$
\begin{equation*}
\mathrm{H} \Psi=\mathrm{E} \Psi \tag{2.1}
\end{equation*}
$$

Here H is the Hamiltonian, a differential operator representing the total energy, which is the sum of kinetic and potential parts,

$$
\begin{equation*}
\mathrm{H}=\mathrm{T}+V \tag{2.2}
\end{equation*}
$$

The first part is the kinetic energy operator (T), which is a sum of differential operators,

$$
\begin{equation*}
T=-\frac{h^{2}}{8 \pi^{2}} \sum_{i} \frac{1}{m_{i}}\left(\frac{\partial^{2}}{\partial x^{2}}+\frac{\partial^{2}}{\partial y^{2}}+\frac{\partial^{2}}{\partial z^{2}}\right) \tag{2.3}
\end{equation*}
$$

The sum is over all particles $i$ (nuclei and electrons) and $m_{i}$ is the mass of particles $i$. $h$ is the Plank's constant. The second part is potential energy operator (V), which is the Coulomb interaction,

$$
\begin{equation*}
V=\sum_{i<j}\left(\frac{e_{i} e_{j}}{r_{i j}}\right) \tag{2.4}
\end{equation*}
$$

where the sum is over pairs of particles ( $i, j$ ) with electric charges $e_{i}, e_{j}$ separated by a distance $\mathrm{r}_{\mathrm{ij}}$. For electrons $\mathrm{e}_{\mathrm{i}}=-e$, while for a nucleus with atomic number $Z_{i}, e_{i}=+Z_{i} \mathrm{e}$.
$E$ is numerical value of the energy of the state; that is the energy relative to a state in which the constituent particles (nuclei and electrons) are at infinite separation and at rest. $\Psi$ is the wave function. It depends on the cartesian coordinates of all particles and also on the spin angular momentum components in a particular direction. The square of the wave function, $\Psi^{2}$, is interpreted as a measurement of the probability distribution of the particles within the molecule.

The acceptable solutions of equation (2.1) must be suitable symmetry under interchange of identical particles. For boson particles, the wavefunction is unchanged; that is symmetric, under such interchange. For fermion particles, the wavefunction must be multiplied by -1 ; that is antisymmetric. Electrons are fermions, so $\Psi$ must be antisymmetric with respect to interchange of the coordinates of any pair of electrons. This is termed antisymmetric principle.

The Schrödinger equation for any molecule has many possible solutions, corresponding to different stationary states. The state with the lowest energy is the ground state.

In molecular system, the Hamiltonian for N electrons and M nuclei is

$$
\begin{equation*}
H=-\sum_{i=1}^{N} \frac{1}{2} \nabla_{i}^{2}-\sum_{A=1}^{M} \frac{1}{2 M_{A}} \nabla_{A}^{2}-\sum_{i=1}^{N} \sum_{A=1}^{M} \frac{Z_{A}}{r_{i A}}+\sum_{i=1}^{N} \sum_{j>i}^{N} \frac{1}{r_{i j}}+\sum_{A=1}^{M} \sum_{B>A}^{M} \frac{Z_{A} Z_{B}}{R_{A B}} \tag{2.5}
\end{equation*}
$$

In the above equation, $\mathrm{M}_{\mathrm{A}}$ is mass of nucleus A and $\mathrm{Z}_{\mathrm{A}}$ is the atomic number of nucleus A. The Laplacian operators $\nabla_{i}^{2}$ and $\nabla_{A}^{2}$ involve differentiation with respect to the coordinates of the $\mathrm{i} t h$ electron and Ath nucleus. $\mathrm{r}_{\mathrm{i}}$ is the distance between the $\mathrm{i} t h$ electron and Ath nucleus. $\mathrm{R}_{\mathrm{AB}}$ is the distance between the A th nucleus and the $\mathrm{B} t h$ nucleus.

### 2.2 Molecular Orbital Theory

Molecular orbital theory is an approach to molecular quantum mechanics, using one-electron function or orbitals to approximate the full wavefunction. The first major step in simplifying the general molecular quantum mechanics is the separation of the nuclear and electronic motions. This is possible because the nuclear masses are much greater than those of the electrons therefore, nuclei move much more slowly. The separation of the problem into two parts is called the adiabatic or BornOppenheimer approximation. ${ }^{34}$ Therefore, the second term of equation (2.5), the kinetic energy of the nuclei, can be neglected and the last term of equation (2.5), the repulsion between the nuclei, can be considered to be constant. The remaining term in equation(2.5), are called the electronic Hamiltonian $\left(\mathrm{H}_{\text {elec }}\right)$ or Hamiltonian describing the motion of N electrons in the field of M point charges,

$$
\begin{equation*}
H_{e l e c}=-\sum_{i=1}^{N} \frac{1}{2} \nabla_{i}^{2}-\sum_{i=1}^{N} \sum_{A=1}^{N} \frac{Z_{A}}{r_{i A}}+\sum_{i=1}^{N} \sum_{j>i}^{N} \frac{1}{r_{i j}} \tag{2.6}
\end{equation*}
$$

The corresponding approximation to the total wavefunction is the multiplication product of electronic wavefunction $\psi_{\text {elec }}\left(\left\{r_{i}\right\} ;\left\{R_{A}\right\}\right)$, which describes the motion of the electrons that explicitly depends on the electronic coordinates, but parametrically depends on the nuclear coordinates and of nuclei wavefunction $\psi_{\text {nucl }}\left(\left\{R_{A}\right\}\right)$, which describes the vibration, rotation, and translation of a molecule.

$$
\begin{equation*}
\Psi\left(\left\{r_{i}\right\} ;\left\{R_{A}\right\}\right)=\psi_{\text {elec }}\left(\left\{r_{i}\right\} ;\left\{R_{A}\right\}\right) \psi_{\text {nucl }}\left(\left\{R_{A}\right\}\right) \tag{2.7}
\end{equation*}
$$

The solution to a Schrödinger equation involving the electronic Hamiltonian is:

$$
\begin{equation*}
H_{\text {elec }} \psi_{\text {elec }}=\varepsilon_{\text {elec }} \psi_{\text {elece }} \tag{2.8}
\end{equation*}
$$

The electronic energy, $\varepsilon_{\text {elec }}$, is also parametric on the nuclear coordinates,

$$
\begin{equation*}
\varepsilon_{\text {elec }}=\varepsilon_{\text {elec }}\left(\left\{R_{A}\right\}\right) \tag{2.9}
\end{equation*}
$$

The total energy for fixed nuclei must also include the constant nuclear repulsion energy,

$$
\begin{equation*}
\varepsilon_{\text {tot }}=\varepsilon_{\text {elec }}+\sum_{A=1}^{M} \sum_{B>A}^{M} \frac{Z_{A} Z_{B}}{R_{A B}} \tag{2.10}
\end{equation*}
$$

The total energy $\varepsilon_{\text {tot }}\left(\left\{R_{A}\right\}\right)$ provides a potential for nuclear motion. This function constitutes a potential energy surface.

The electronic Hamiltonian in equation (2.6) depends only on spatial coordinates of the electrons. To describe the behavior of an electron, it is necessary to specify its spin. In the context of nonrelativistic theory, there are two spin function $\alpha(\omega)$ and $\beta(\omega)$, corresponding to spin up and spin down, respectively. From each spatial, $\psi(r)$, one can form two different spin orbitals, $\chi(x)$

$$
\chi(x)=\left\{\begin{array}{l}
\chi(x)=\psi(r) \alpha(\omega)  \tag{2.11}\\
o r \\
\chi(x)=\psi(r) \beta(\omega)
\end{array}\right.
$$

The four coordinates of electron is denoted by x ,

$$
\begin{equation*}
x=\{r, \omega\} \tag{2.12}
\end{equation*}
$$

The wavefunction for an $N$-electron system is then a function of $x_{1}, x_{2}, \ldots, x_{N}$. This is $\psi\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{N}}\right)$. Wavefunction must corresponds to the antisymmetric or Pauli exclusion principle, a many electron wavefunction must be antisymmetric with respect to the interchange of the coordinates $x$ (both space and spin) of any two electrons, i.e.,

$$
\begin{equation*}
\psi\left(\mathrm{x}_{1}, \ldots, \mathrm{x}_{i}, \ldots, \mathrm{x}_{j}, \ldots, \mathrm{x}_{N}\right)=-\psi\left(\mathrm{x}_{1}, \ldots, \mathrm{x}_{j}, \ldots, \mathrm{x}_{i}, \ldots, \mathrm{x}_{N}\right) \tag{2.13}
\end{equation*}
$$

So the electronic wavefunction must be written as Slater determinant of spin orbital,

$$
\Psi\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{N}\right)=(N!)^{-1 / 2}\left|\begin{array}{cccc}
\chi_{1}\left(x_{1}\right) & \chi_{j}\left(x_{1}\right) & \cdots & \chi_{\mathrm{k}}\left(x_{1}\right)  \tag{2.14}\\
\chi_{1}\left(x_{2}\right) & \chi_{j}\left(x_{2}\right) & \cdots & \chi_{k}\left(x_{2}\right) \\
\vdots & \vdots & & \vdots \\
\chi_{i}\left(x_{N}\right) & \chi_{j}\left(x_{N}\right) & \cdots & \chi_{k}\left(x_{N}\right)
\end{array}\right|
$$

or short notation,

$$
\begin{equation*}
\Psi\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{N}\right)=\left|\chi_{1}\left(x_{1}\right) \chi_{j}\left(x_{2}\right) \ldots \chi_{k}\left(x_{N}\right)\right\rangle \tag{2.15}
\end{equation*}
$$

where the factor $(\mathrm{N}!)^{1 / 2}$ is a normalization factor.

### 2.3 The Hartree-Fock Approximation

The simplest antisymmetric wavefunction, which can be used to describe the ground state of the an N -electron system, $\Psi_{0}$, is a single Siater determinant,

$$
\begin{equation*}
\Psi_{0}=\left|\chi_{1} \chi_{2} \ldots \chi_{a} \chi_{b} \cdots \chi_{N}\right\rangle \tag{2.16}
\end{equation*}
$$

The variation principle states that the best wavefunction of this functional form is the one which gives the lowest possible energy,

$$
\begin{equation*}
\mathrm{E}_{0}=\left\langle\Psi_{0}\right| H\left|\Psi_{0}\right\rangle \tag{2.17}
\end{equation*}
$$

where H is the full electronic Hamiltonian. The variational flexibility in the wavefunction (2.16) is in the choice of spin orbitals, one can derive eigenvalue equation, called the Hatree-Fock equation which determines the optimal spin orbitals of the form

$$
\begin{equation*}
\mathrm{f}(\mathrm{i}) \chi\left(\mathrm{x}_{\mathrm{i}}\right)=\varepsilon \chi\left(\mathrm{x}_{\mathrm{i}}\right) \tag{2.18}
\end{equation*}
$$

where $f(i)$ is an effective one-electron operator, called the Fock operator, of the form

$$
\begin{equation*}
\mathrm{f}(\mathrm{i})=-\frac{1}{2} \nabla_{\mathrm{i}}^{2}-\sum_{\mathrm{A}=1}^{\mathrm{M}} \frac{\mathrm{Z}_{\mathrm{A}}}{\mathrm{r}_{\mathrm{iA}}}+\mathrm{V}^{\mathrm{HF}}(\mathrm{i}) \tag{2.19}
\end{equation*}
$$

where $\mathrm{V}^{\mathrm{HF}}(\mathrm{i})$ is the average potential experienced by the i th electron due to the presence of the other electrons. The essence of the Hatree-Fock approximation is to replace the complicate many-electron problem by one-electron problem in which electron-electron repulsion is treated in an average way.

The Hartree-Fock potential $\mathrm{v}^{\mathrm{HF}}$ (i), or equivalently the "field" seen by the $i t h$ electron, depends on the spin orbitals of the other electrons. Thus the Hartree-Fock equation (2.18) is nonlinear and must be solved iteratively. The procedure for solving the Hartree-Fock equation is called the self-consistent-field (SCF) method.

From equation (2.19), the best (Hatree-Fock) spin orbitals is the Hartree-Fock integro-differential equation

$$
\begin{equation*}
h(1) \chi_{a}(1)+\sum_{b \neq a}^{N}\left[\int d x_{2}\left|x_{b}(2)\right|^{2} r_{12}^{-1}\right] \chi_{a}(1)-\sum_{b \neq a}^{N}\left[\int d x_{2} \chi_{b}^{*}(2) \chi_{a}(2) r_{12}^{-1}\right] \chi_{b}(1)=\varepsilon_{a} \chi_{a}(1) \tag{2.20}
\end{equation*}
$$

or

$$
\begin{equation*}
\left[h(\mathrm{I})+\sum_{b \neq a}^{N} J_{b}(1)-\sum_{b \neq a}^{N} K_{b}(1)\right] \chi_{a}(1)=\varepsilon_{a} \chi_{a}(1) \tag{2.21}
\end{equation*}
$$

where $h(1)$ is core-Hamiltonian operator

$$
\begin{equation*}
h(1)=-\frac{1}{2} \nabla_{1}^{2}-\sum_{A=1}^{M} \frac{Z_{A}}{r_{1 A}} \tag{2.22}
\end{equation*}
$$

$\mathrm{J}_{\mathrm{b}}(1)$ is the coulomb operator

$$
\begin{equation*}
\mathrm{J}_{\mathrm{b}}(1)=\int \mathrm{dx} \mathrm{x}_{2}\left|\chi_{\mathrm{b}}(2)\right|^{2} \mathrm{r}_{12}^{-1} \tag{2.23}
\end{equation*}
$$

$\mathrm{K}_{\mathrm{b}}(1)$ is the exchange operator

$$
\begin{equation*}
\mathrm{K}_{\mathrm{b}}(1)=\int \mathrm{dx}_{2} \chi_{\mathrm{b}}^{*}(2) \mathrm{r}_{12}^{-1} \mathrm{P}_{12} \chi_{\mathrm{b}}(2) \tag{2.24}
\end{equation*}
$$

Therefore, the Fock operator $f(1)$ can be written as

$$
\begin{equation*}
f(1)=h(1)+\sum_{b=1}^{N}\left[J_{a}(1)-K_{b}(1)\right] \tag{2.25}
\end{equation*}
$$

and the Hartree-Fock potential $V^{\mathrm{HF}}(1)$,

$$
\begin{equation*}
\mathrm{V}^{\mathrm{HF}}(1)=\sum_{\mathrm{b}=1}^{\mathrm{N}}\left[\mathrm{~J}_{\mathrm{a}}(1)-\mathrm{K}_{\mathrm{b}}(1)\right] \tag{2.26}
\end{equation*}
$$

the orbital energy $\varepsilon_{a}$,

$$
\begin{equation*}
\varepsilon_{a}=\int \chi_{a}|h| \chi_{a} d \tau+\sum_{b=1}^{N}\left[\int \chi_{a} \chi_{a} r_{12}^{-1} \chi_{b} \chi_{b} d \tau_{1} d \tau_{2}-\int \chi_{a} \chi_{b} r_{12}^{-1} \chi_{b} \chi_{a} d \tau_{1} d \tau_{2}\right] \tag{2.27}
\end{equation*}
$$

and Hartree-Fock energy

$$
\begin{gather*}
E_{0}=\sum_{a=1}^{N} \int \chi_{a}|h| \chi_{a} d \tau+\frac{1}{2} \sum_{a=1}^{N} \sum_{b=1}^{N}\left[\int \chi_{a} \chi_{a} r_{12}^{-1} \chi_{b} \chi_{b} d \tau_{1} d \tau_{2}-\int \chi_{a} \chi_{b} r_{12}^{-1} \chi_{b} \chi_{a} d \tau_{1} d \tau_{2}\right]  \tag{2.28}\\
E_{0}=\sum_{a=1}^{N} \varepsilon_{a}+\frac{1}{2} \sum_{a=1}^{N} \sum_{b=1}^{N}\left[\int \chi_{a} \chi_{a} r_{12}^{-1} \chi_{b} \chi_{b} d \tau_{1} d \tau_{2}-\int \chi_{a} \chi_{b} r_{12}^{-1} \chi_{b} \chi_{a} d \tau_{1} d \tau_{2}\right] \tag{2.29}
\end{gather*}
$$

For closed-shell restricted Hartree-Fock wavefunction

$$
\begin{gather*}
\left|\Psi_{0}\right\rangle=\left|\chi_{1} \chi_{2} \chi_{3} \chi_{4} \ldots \chi_{N-1} \chi_{N}\right\rangle \\
=\left|\Psi_{1} \bar{\Psi}_{1} \Psi_{2} \bar{\Psi}_{2} \ldots \Psi_{N / 2} \bar{\Psi}_{N / 2}\right\rangle \\
E_{0}=2 \sum_{a=1}^{N / 2} \int \psi_{a}|h| \psi_{a} d \tau+\sum_{a=1}^{N / 2 N / 2} \sum_{b=1}\left[2 \int \psi_{a} \psi_{a} r_{12}^{-1} \psi_{b} \psi_{b} d \tau_{1} d \tau_{2}-\int \psi_{a} \psi_{b} r_{12}^{-1} \psi_{b} \psi_{a} d \tau_{1} d \tau_{2}\right] \\
\mathbb{E}_{0}=2 \sum_{a=1}^{N / 2} h_{a a}+\sum_{a=1}^{N / 2} \sum_{b=1}^{N / 2}\left(2 J_{a b}-K_{a b}\right) \tag{2.30}
\end{gather*}
$$

or
where $\quad J_{a b}=\int \psi_{a} \psi_{a} r_{12}^{-1} \psi_{b} \psi_{b} d \tau_{1} d \tau_{2} \quad$ and $\quad K_{a b}=\int \psi_{a} \psi_{b} r_{12}^{-1} \psi_{b} \psi_{a} d \tau_{1} d \tau_{2}$
Equation (2.30) is the eliminated spin form, the calculation of molecular orbitals become equivalent to the problem of solving the spatial integro-differential equation

$$
\begin{equation*}
f\left(r_{l}\right) \psi\left(r_{l}\right)=\varepsilon_{\mathrm{i}} \psi\left(r_{l}\right) \tag{2.31}
\end{equation*}
$$

Solving this equation numerically, Roothaan introduces a set of known basis functions ( $\phi_{\mu}$ ) and $\left\{\phi_{\mu}(r), \mu=1,2, \ldots, K\right\}$ expand the unknown molecular orbitals $\left(\psi_{i}\right)$ in the linear expansion of these functions,

$$
\begin{equation*}
\psi_{i}=\sum_{\mu=1}^{K} C_{\mu i} \phi_{\mu} \quad \mathrm{i}=1,2, \ldots, \mathrm{~K} \tag{2.32}
\end{equation*}
$$

The quality of the molecular orbitals is related to the quality of the basis set, set of basis functions used.

From equation (2.31), the problem of calculating the Hartree-Fock molecular orbitals reduces to the problem of calculating the set of expansion coefficients $\mathrm{C}_{\mu \mathrm{i}}$.

By substitution the linear expansion (2.32) into Hartree-Fock equation(2.31) and using the index $v$, gives

$$
\begin{equation*}
f(1) \sum_{v=1}^{K} C_{v i} \phi_{v}(1)=\varepsilon_{i} \sum_{v=1}^{K} C_{v i} \phi_{v}(1) \tag{2.33}
\end{equation*}
$$

then multiply by $\phi_{\mu}^{*}(1)$ on the left and integrate

$$
\begin{equation*}
\sum_{\nu=1}^{K} C_{v i} \int d r_{l} \phi_{\mu}^{*}(1) f(1) \phi_{v}(1)=\varepsilon_{i} \sum_{\nu=1}^{K} C_{v i} \int d r_{1} \phi_{\mu}^{*}(1) \phi_{\nu}(1) \tag{2.34}
\end{equation*}
$$

and define two matrices, are the overlap matrix S , has elements

$$
\begin{equation*}
S_{\mu v}=\int d r_{1} \phi_{\mu}^{*}(1) \phi_{v}(1) \tag{2.35}
\end{equation*}
$$

and the Fock matrix $F$, has elements

$$
\begin{equation*}
F_{\mu \nu}=\int d r_{1} \phi_{\mu}^{*}(1) f(1) \phi_{v}(1) \tag{2.36}
\end{equation*}
$$

Therefore, the integrated Hatree-Fock equation is written as

$$
\begin{equation*}
\sum_{\nu=1}^{K} F_{\mu \nu} C_{v i}=\varepsilon_{i} \sum_{\nu=1}^{K} S_{\mu \nu} C_{v i} \quad \mathrm{i}=1,2, \ldots, \mathrm{~K} \tag{2.37}
\end{equation*}
$$

These are the Roothaan-Hall equations, proposed by Roothaan ${ }^{35}$ and Hall ${ }^{36}$ which can be written as the single matrix equation

$$
\begin{equation*}
F C=S C \varepsilon \tag{2.38}
\end{equation*}
$$

Where C is a $\mathrm{K} \times \mathrm{K}$ square matrix of the expansion coefficient $c_{\mu i}$

$$
C=\left(\begin{array}{cccc}
c_{11} & c_{12} & \cdots & c_{1 k}  \tag{2.39}\\
c_{21} & c_{22} & \cdots & c_{2 k} \\
\vdots & \vdots & & \vdots \\
c_{K 1} & c_{K 2} & \cdots & c_{K K}
\end{array}\right)
$$

and $\varepsilon$ is a diagonal matrix of the orbital energies $\varepsilon_{i}$,

$$
\begin{gather*}
\varepsilon=\left(\begin{array}{cccc}
\varepsilon_{1} & 0 & \cdots & 0 \\
& \varepsilon_{2} & & \\
& & \ddots & \\
0 & & \cdots & \varepsilon_{k}
\end{array}\right)  \tag{2.40}\\
F_{\mu \nu}=H_{\mu \nu}^{c o r e}+G_{\mu \nu} \tag{2.41}
\end{gather*}
$$

where $H_{\mu \nu}^{c o r e}$ is the Hamiltonian matrix

$$
\begin{equation*}
H_{\mu \nu}^{c o r e}=\int d r_{1} \phi_{\mu}^{*}(1) h(1) \phi_{\nu}(1) \tag{2.42}
\end{equation*}
$$

$G_{\mu \nu}$ is the two-electron part of the Fock matrix

$$
\begin{equation*}
G_{\mu \nu}=\sum_{\lambda=1}^{N / 2 N / 2} \sum_{\sigma=1} P_{\lambda \sigma}\left[(\mu \nu \mid \sigma \lambda)-\frac{1}{2}(\mu \lambda \mid \sigma \nu)\right] \tag{2.43}
\end{equation*}
$$

$P_{\lambda \sigma}$ is the density matrix

$$
\begin{equation*}
P_{\mu v}=2 \sum_{\mathrm{a}}^{\mathrm{N} / 2} \mathrm{C}_{\mu \mathrm{a}} \mathrm{C}_{\mathrm{va}}^{*} \tag{2.44}
\end{equation*}
$$

and

$$
\begin{equation*}
(\mu \nu \mid \lambda \sigma)=\int d r_{1} d r_{2} \phi_{\mu}^{*}(1) \phi_{\nu}(1) r_{12}^{-1} \phi_{\lambda}^{*}(2) \phi_{\sigma}(2) \tag{2.45}
\end{equation*}
$$

For solving the Roothaan-Hall equation, iterative process called a Self. Consistent Field (SCF) procedure is required. The outline of mathematical steps to solve the Roothaan-Hall equations for a closed-shell system are shown in the Figure 2.1 .

Figure 2.1 Sequence of program step required for the solution of the Roothaan-Hall equations for closed-shell, Self Consistent Field procedure.

### 2.4 Basis Set

The basis set most commonly used in quantum mechanical calculations are composed of atomic functions. The next approximation involves expressing the molecular orbitals as linear combinations of a predefined set of one-electron function. An individual molecular orbitals is defined as:

$$
\begin{equation*}
\psi_{i}=\sum_{\mu=1}^{N} c_{\mu i} \phi_{\mu} \tag{2.46}
\end{equation*}
$$

where the coefficients $c_{\mu i}$ are known as molecular orbital expansion coefficients. The $\phi_{1}, \phi_{2}, \ldots, \phi_{N}$ are the orthogonal function with known expression. The set of this function is called "basis set".

The best solution to the approximation of MO could theoretically be obtained by the use of an infinite and complete set of $b$ asis functions. The most often $u$ sed mathematical expressions for the basis functions are the Slater-type orbital (STO) and the Gaussian-type orbitals (GTO).

The Slater-type orbitals has the form

$$
\begin{equation*}
\phi^{S T O}=r^{n-1} e^{-\zeta r} Y_{l}^{m}(\theta, \phi) \tag{2.47}
\end{equation*}
$$

where $n, l, m$ are quantum numbers and $\varsigma$ is orbital exponent. The $r, \theta, \phi$ are the spherical polar coordinates. This Slater functions were introduced by Slater ${ }^{37}$ and extremely close in form to the hydrogenic orbitals. In the past, they were mostly used for the calculations of small molecules. Their advantage is that only few functions are needed for a good description, but not suited to the numerical work, and their use in practical molecular orbital calculations has been limited.

The Gaussian-type orbitals has the form

$$
\begin{equation*}
\phi^{G T O}=x^{a} y^{b} z^{c} e^{-\alpha r^{2}} \tag{2.48}
\end{equation*}
$$

where $a, b, c$ are integer numbers and $\alpha$ is the orbital exponent. The $x, y, z$ are the cartesian coordinates. The GTO were introduced into molecular orbital calculations by Boy. ${ }^{38}$ They are less satisfactory than STO as representations of a tomic orbital, particularly because they do not have a cusp at the origin (Figure 2.2). Due to this deficiency more than one GTOs are often required for a good description. At present,
most calculation performed uses GTOs instead of STOs since the computation of GTO is much faster than that of the STO. So, as many GTO functions, which yields the same quality to the STO can be computed in the fraction of time.

Figure 2.2 The cusp of Slater function.

### 2.4.1 Minimal Basis Set

A minimal basis set is a representation that contains just the number of functions that are required to accommodate all the filled orbitals in each atom. In practice, a minimal basis set normally includes all of the atomic orbitals in the shell. Thus, for hydrogen and helium a single s-type function would be required. For elements from lithium to neon the $1 \mathrm{~s}, 2 \mathrm{~s}$ and 2 p functions are used and so on. The basis sets STO-nG for example, STO-3G, STO-4G, are all minimal basis sets in which $n$ Gaussian functions are used to represent the Slater orbital. The minimal basis sets are well known to accompany with several deficiencies. There are particular problems with compounds containing atoms at the end of a period, such as oxygen or fluorine. Such atoms are described using the same number of basis functions as the atoms at the beginning of the period despite they have more electrons. A minimal basis set only contains one function per atomic orbital. Since the radial exponents are not allowed to vary during the calculation, the orbital cannot expand or contract in size in accordance with the molecular environment.

### 2.4.2 Extended Basis Set

The problems with minimal basis sets can be addressed if more than one function is used for each orbital. For STO, a basis set which doubles the number of functions in the minimal basis set is described as double zeta basis. The double or triple or more of STO minimal basis function allows the linear combination of the 'contracted'(large exponent) and the 'diffuse'(small exponent) functions which gives an overall result that is intermediate between the two. In other words, the size of orbital can be modified during the course of calculation. An alternative to the double zeta basis approach is to double the number of functions used to describe the valence electrons but to keep a single function for the inner shells called "split valence double zeta basis". For GTO, the similar notation to STO can also be used. The 3-21G exemplifies the notation used for such split valence double zeta basis sets. In this basis set, three Gaussian functions are used to describe the core orbitals. The valence electrons are also represented by three Gaussian; the contracted part by two Gaussian and the diffuse part by one Gaussian. The most commonly used split valence basis sets are 3-21G, 6-31G and D95V (Dunning's split valence double zeta basis).

### 2.4.3 Polarized Basis Set

Simply increasing the number of basis functions does not necessarily improve the model. This possibly leads to a wholly erroneous result, particularly for molecules with strongly anisotropy charge distribution. This distortion can be considered to correspond to mixing p-type character into the 1 s orbital of the isolated atom, to give a form of sp hybrid. In a similar manaer, the unoccupied d orbitals introduce asymmetry into p orbital. In other words, the addition of p function for H atom and $d$ function for heavier atom enable orbitals on nuclei to polarize and form bond. These functions, p for hydrogen and d for $1^{\text {st }}$ and $2^{\text {nd }}$ row element, have a higher angular momentum and they are called the "polarization" function. An a sterisk (*) indicates the use of polarization basis functions. Thus, $6-31 \mathrm{G}^{*}$ refers to a $6-31 \mathrm{G}$ basis set with polarization functions on the heavy (non-hydrogen) atoms. Two asterisks, such as $6-31 \mathrm{G}^{* *}$ indicate the use of polarization functions on hydrogen and heavy atoms.

### 2.4.4 Basis set Incorporating Diffuse Function

Another deficiency of the basis sets is their inability to deal with species that have a significant amount of electron density away from the nuclear centers such as anions and molecules containing lone pair. This failure arises because the amplitudes of the Gaussian basis functions are rather low far from the nuclei. To remedy this deficiency highly diffuse functions i.e. functions with very small exponent, is added to the basis set. These basis sets are denoted using a ' + '; thus the $3-21+G$ basis set contains an additional single set of diffuse s- and p-type Gaussian functions for heavy atoms. A ' ++ ' indicates that the diffuse functions are included for both hydrogen and heavy atoms such $6-31++\mathrm{G}$.

### 2.5 Population Analysis

The probability of finding an electron in various regions of space, $\rho(\mathrm{r})$, is called the charge density and is defined as,

$$
\begin{equation*}
\rho(r)=\sum_{\mu=1}^{N / 2} \sum_{\nu=1}^{N / 2} P_{\mu \nu} \phi_{\mu}(r) \phi_{v}^{*}(r) \tag{2.49}
\end{equation*}
$$

Therefore, the total number of electrons ( N ) is

$$
\begin{equation*}
N=2 \sum_{a=1}^{N / 2} \int d r\left|\psi_{a}(r)\right|^{2} \tag{2.50}
\end{equation*}
$$

By substitution eq. (2.32) into eq.(2.50) and using the index $\mu$, the equation(2.50) becomes

$$
\begin{equation*}
N=\sum_{\mu=1}^{N / 2 N / 2} \sum_{v=1} P_{\mu v} S_{v \mu}=\sum_{\mu=1}^{N / 2}(P S)_{\mu \mu /}=t r P S \tag{2.51}
\end{equation*}
$$

$(P S)_{\mu \mu}$ indicated the number of electrons to be associated $\phi_{\mu}$. This is called a Mulliken population analysis. ${ }^{39}$ The net charge of the an atom $\left(q_{\mathrm{A}}\right)$ is given by

$$
\begin{equation*}
q_{A}=Z_{A}-\sum_{\mu E A}(P S)_{\mu \mu} \tag{2.52}
\end{equation*}
$$

where $\mathrm{Z}_{\mathrm{A}}$ is the charge of atomic nucleus A .

One important property of molecule involving the electrons distribution is dipole moment, $\mu$. The dipole moment of molecule can be calculated as

$$
\begin{equation*}
\mu=\left\langle\Psi_{0}\right|-\sum_{i=1}^{N} r_{i}\left|\Psi_{0}\right\rangle+\sum_{A} Z_{A} R_{A} \tag{2.53}
\end{equation*}
$$

where the first term is the contribution of the electrons, of charge -1 , and the second term is the contribution of the nuclei, $\mathrm{Z}_{\mathrm{A}}$ to the dipole moment. The electronic dipole moment operator $-\sum_{i=1}^{N} r_{i}$, a sum of one-electron operators.

Therefore,

$$
\begin{equation*}
\mu=-\sum_{\lambda=1}^{N / 2 N / 2} \sum_{\sigma=1}^{N} P_{\lambda \sigma}(\lambda|r| \sigma)+\sum_{A} Z_{A} R_{A} \tag{2.54}
\end{equation*}
$$

A vector equation with components (for example the $x$ component) is

$$
\begin{equation*}
\mu_{x}=-\sum_{\lambda=1}^{N / 2} \sum_{\sigma=1}^{N / 2} P_{i \sigma}(\lambda|x| \sigma)+\sum_{A} Z_{A} X_{A} \tag{2.55}
\end{equation*}
$$

where

$$
\begin{equation*}
(\lambda|x| \sigma)=\int d r \phi_{\lambda}^{*}\left(r_{1}\right) x_{1} \phi_{\sigma}\left(r_{1}\right) \tag{2.56}
\end{equation*}
$$

With the same manner, $\mu_{y}$ and $\mu_{z}$ can be aiso computed.

## CHAPTER 3

## STRUCTURE AND BIOLOGICAL DATA

### 3.1 Chemical Structure of Tricyclic 1,2,4-trioxane

An empirical formula of compound is $\mathrm{C}_{12} \mathrm{H}_{20} \mathrm{O}_{4}$ with a molecular weight of 228.3, a melting point of $74-75{ }^{\circ} \mathrm{C}$ and a density of $1.275 \mathrm{~g} / \mathrm{cm}^{3}$. Its stereochemistry and atomic numbering scheme according to the IUPAC of artemisinin is shown in Figure 3.1. ${ }^{40}$

Figure 3.1 Stereochemistry and atomic numbering scheme of tricyclic 1,2,4-trioxanes.

### 3.2 Structures and Antimalarial Activities of Tricyclic 1,2,4-trioxane derivatives

Totally 32 derivatives of tricyclic 1,2,4-trioxane with significantly different structures and biological activities taken from literatures ${ }^{41-44}$ were used in this study. The activities were measured in vitro against the NF54 strain of Plasmodium falciparum, a chloroquine-sensitive strain, as $\mathrm{IC}_{50}$ values, an inhibitory concentration of a compound required for $50 \%$ inhibition of parasitemia. Since the biological data arose from different literatures, there were an inconsistency from individual experimental testing procedures. For example, the activities of artemisinin measured in references $41,42,43$ and 44 , are 11, 9.2, 8.5 and 9.9 nM , respectively. Therefore, antimalarial activities of all compounds have to be converted into values in the same scale. For this purpose, the activity of artemisinin in reference $41\left(\mathrm{IC}_{50}=11 \mathrm{nM}\right)$ was set as a standard value. Then, the activity
of artemisinin from reference 42-44 was compared to the standard values to give a scaling factor as shown in equation (3.1). Subsequently, the activity of each compound in reference $42-44$ was multiplied by the corresponding scaling factor. Finally, the antimalarial activity is calculated in logarithm unit by equation (3.2).

$$
\begin{align*}
& \text { Scaling Factor }(S)= \frac{\mathrm{IC}_{50} \text { of artemisinin in reference[41] }}{\mathrm{IC}_{50} \text { of artemisinin in reference[42 or 43 or 44] }}  \tag{3.1}\\
&\text { Activity } \left.=\log \frac{1}{\mathrm{~S}^{*} \mathrm{IC}_{50}(\text { in molarunit })}\right) \tag{3.2}
\end{align*}
$$

The structures and biological data of 32 compounds with the reference sources are given in Table 3.1-3.4. All the compounds have different substituent groups, which can be possible effects of structural differences in tricyclic 1,2,4-trioxane compounds concerning their biological activities. Compounds 1-15 have substituent groups at the $\mathrm{C}_{3}$ position in which compounds 1-4 have alkyl substituent groups while compounds 5-15 have aryl substituent groups. Preliminary analysis of the raw dataset indicated interesting features as follows. Compounds with aryl substituent groups are more potent than those with alkyl substituents. Comparing compound 10 to compounds 11 and 12, a p-fluoro substituent in compound 12 enhances the antimalarial activity while an o-methyl substituent in compound 11 decrease the antimalarial potency. A comparison between compounds 6 and 12 showed that the nature of the halogen substituent, chloro, fluoro has significant effect. Remarkably, compounds 13-15, oxygen-containing benzylic trioxanes are potent antimalarials. Compounds 16-2 have substituent groups at the $\mathrm{C}_{12}$ position. The sulfone trioxanes (compounds 19-21) have higher antimalarial potencies than the sulfides (compounds 16-18). Compounds 22-24 have substituent groups at the $\mathrm{C}_{4}$ position. Compound 24 with $p$-fluorobenzyl ether substituent is the most active compound in this group. Compounds 25-32 have substituent groups at the $\mathrm{C}_{4}$ and/or $\mathrm{C}_{8 \mathrm{a}}$ positions and these compounds have rather high activities. Comparisons of compounds 25 to 28, compounds 26 to 29 and compounds 27 to 31, in which each pair have the same substituent groups at the $\mathrm{C}_{8 \mathrm{a}}$ position but different substituent groups at the $\mathrm{C}_{4}$ position,
show that changing of hydrogen atom at the $\mathrm{C}_{4}$ position to a methyl group can increase antimalarial activities.

### 3.3 Geometry Optimization and Atomic Charge Calculation

Quantum chemical calculations have been proven as helpful means to calculate directly molecular properties and geometries. The validity of these methods can be examined by comparing structures and properties with those of experimental results. As an experimental structure of most compounds used in this study is not available, quantum chemical calculations were applied to determine the geometry of all compounds. However, it is necessary to examine/which level of calculation provides the more accurate geometry compared to the x-ray crystallographic data.

A9starting geometry of tricyclic 1,2,4-trioxane was obtained from the crystallographic structure. ${ }^{40}$ In our previous study, ${ }^{40}$ artemisinin structure was optimized using CNDO, AM1, Hartree Fock (HF) with 3-21G and 6-31G(d,p) basis sets, and Density Functional Theory (DFT) with B3LYP functional and 6-31G(d,p) basis set. All optimized structures were compared to the X-ray structure. The results indicated that the Hartree Fock (HF) with 3-21G basis set (HF/3-21G) is the lowest level of theory that
gives geometrical parameters within acceptable accuracy of the X-ray data. Since tricyclic 1,2,4-trioxane has very similar structure to artemisinin, the HF/3-21G method should also be an appropriate method for geometry optimization of tricyclic 1,2,4trioxane compounds. Therefore, the tricyclic 1,2,4-trioxane compound was optimized at the HF/3-21G level and then was compared to the X-ray structure in order to confirm our assumption (see Table 3.5).

Table 3.5 Comparison of important structural parameters of tricyclic 1,2,4-trioxane as obtained from the X-ray and HF/3-21G optimization method.

| $\mathrm{C}_{50}-\mathrm{C}_{5}-\mathrm{C}_{4}-\mathrm{C}_{3}$ | 58.5 | 62.8 |
| $\mathrm{O}_{2}-\mathrm{C}_{3}-\mathrm{C}_{4}-\mathrm{C}_{5}$ | 95.0 | 97.3 |
| $\mathrm{C}_{4}-\mathrm{C}_{3}-\mathrm{O}_{2}-\mathrm{O}_{1}$ | 50.8 | 47.9 |

The results show that HF/3-21G can reproduce most of the structural parameters very reliably in comparison to the X-ray structure. Thus, the HF/3-21G level of theory was used for the geometry optimizations of all tricyclic 1,2,4-trioxane derivatives. All calculations were done using the Gaussian 98 software. ${ }^{46}$

## CHAPTER 4

## CLASSICAL-QSAR

### 4.1 Introduction

Quantitative structure-activity relationship (QSAR) is a mathematical relationship linking chemical structure and pharmacological activity in a quantitative manner for a series of compounds. The mathematical methods, used in QSAR include various regression and pattern recognition techniques. QSAR is taken to be equivalent to chemometrics or multivariate statistical data analysis. QSAR study involves selecting the representations of molecules that can explain the activity induced in the biological system. These representations are generally referred to physicochemical parameters. Physicochemical properties which usually relate to activity of molecule are hydrophobic, steric and electronic properties, etc.

### 4.1.1 Classical QSAR

Classical QSAR techniques were original QSAR approach, attempting to relate physicochemical properties to pharmacological effect. The first QSAR study was done in 1893 by Charles Richet. ${ }^{47}$ A few years later Meyer and Overton independently found linear relationships between lipophilicity (expressed as solubility or oil-water partition coefficient) and biological effect. In 1964, Hansch and Fujita ${ }^{48}$ published their studies on quantitative relationships between physicochemical properties (i.e., lipophilicity substituent, electronic substituent, and reaction constants) and biological activities. Free and Wilson developed a model of additive group contributions to biological activity values. ${ }^{49}$ In principle, the classical QSAR approaches are established by considering physicochemicalproperties related with the activities of a structurally homologous series of ligands and are solved by means of statistical techniques like linear and non-linear regression, cluster and discriminant analysis. The most commonly used method is multiple linear regression (MLR) analysis for creating QSAR model.

### 4.1.1.1 Hydrophobicity Properties

The hydrophobic or lipophilic character of a drug can be measured experimentally by testing the drugs's relative distribution in an octanol/water mixture. Hydrophobic molecules prefer to dissolve in 1-octanol layer of this two phase system, whereas hydrophilic molecules prefer the aqueous layer. The relative distribution is known as the partition coefficient (P) and is obtained from the following equation (4.1):

$$
\begin{equation*}
\mathrm{P}=\frac{\text { Concentration of a solute in 1-octanol }}{\text { Concentration of a solute in aqueous phase }} \tag{4.1}
\end{equation*}
$$

From the definition of P , it is obvious that hydrophobic compounds have a high P value, whereas hydrophilic compounds have a low P value. However, the main drawback of measuring P experimentally is that the compound has to be synthesized. Moreover, the measurement is sometimes not easy. Therefore, it is much better to calculate P theoretically.

Partition coefficient can be calculated by knowing the contribution that various substituent make to hydrophobicity. This contribution is known as the Hansch substituent hydrophobicity constant $(\pi) .{ }^{50}$ Partition coefficients are measured for a standard compound with and without a substituent (x). The hydrophobicity constant ( $\pi_{\mathrm{x}}$ ) for the substituent ( x ) is then obtained using the following equation (4.2):

$$
\begin{equation*}
\pi_{x}=\log P_{x}-\log P_{H} \tag{4.2}
\end{equation*}
$$

where $P_{x}$ and $P_{H}$ are the partition coefficients for the standard compound with and

A positive value of $\pi$ indicates that the substituent is more hydrophobic. These $\pi$ values are characteristic for the substituents and can be used to calculate how the partition coefficient of a drug would be affected by adding these substituents. In addition, partition coefficient is additive constitutive parameter, like some other molecular properties. Log P is highly correlated with a diversity of biological activities and plays a significant role in the interactions between drugs and their receptors. The overall hydrophobicity of a molecule can be measured by its partition coefficient (logP) in polar/nonpolar heterogeneous reference system. A
comprehensive study of partition experiments in the octanol/water system leads to the definition of hydrophobic contributions of single atom in their specific structural environment. ${ }^{51}$ These atomic partial values can be regarded as fragmental increments, $f_{i}$, to the total lipophillicity given by $\log P$ in equation (4.3).

$$
\begin{equation*}
\log P=\sum_{i} f_{i} \tag{4.3}
\end{equation*}
$$

### 4.1.1.2 Steric Properties

The measure of steric factor can be obtained by several parameters e.g., molar refractivity (MR). This molar refractivity is calculated from the following equation (4.4):

$$
\begin{equation*}
M R=\frac{M W}{d} \cdot \frac{n^{2}-1}{n^{2}+2} \tag{4.4}
\end{equation*}
$$

where n is refractive index, MW is a molecular weight, and d is a density. The term $\frac{M W}{d}$ defines a volume, while the $\frac{\left(n^{2}-1\right)}{\left(n^{2}+2\right)}$ term describes how easily the substituent can be polarized. This is particularly significant if the substituent has $\pi$ electrons or lone pair of electrons. MR is also an additive constitutive molecular property, like $\log P$ parameter. MR is correlated with lipophilicity, molar volume and steric bulk. Due to its $\frac{M W}{d}$ component, it is indeed related to volume and size of a substituent. The refractive index, related correlation term in MR, account polarizability and thus for the size and the polarity of a certain group. The larger the polar part of molecule is, the larger its MR value will be. Molar refractivity normally has significant contributions to the QSAR equations of ligand-enzyme interactions.

Other widely used steric descriptors for biological activity investigation are bond length, bond angle, and dihedral angle parameters, which can be simply measured from the structure, are members of this group. The topological indices, which are calculated using the chemical graph theory ${ }^{52}$ as the basis, are also widely used. Examples of these indices are the Wiener index, ${ }^{53}$ molecular connectivity indices (Chi), ${ }^{54}$ valence-modified molecular connectivity indices (ChiV), ${ }^{54}$ and molecular shape indices (Kарра). ${ }^{54}$ The Wiener index is the sum of distances between all pairs of heavy atoms in the molecule. The Chi and ChiV indices reflect
the atom identities, bonding environments, and number of bonding hydrogens. Molecules that are drawn without hydrogen atoms can be decomposed into fragments of length $m$, which may be divided into four different categories: Path, Cluster, Path/cluster, and Ring. The spread and numbers of substructure fragment membership for each category is determined by molecular connectivity. The main difference between these two types of indices is that only the valence electrons involved in skeletal bonding (sigma orbitals) are counted for the Chi indices whereas all the valence electrons are counted in the ChiV indices to take into account electron configuration of the atom. The kappa indices are molecular shape indices based on the assumption that the shape of a molecule is a function of the number of atoms and their bonding relationship (without considering hydrogen atoms). The values are derived from counts of one-bond (Kappa 1), two-bond (Kappa 2), and three-bond (Карра 3) fragments, each count being relative to fragment counts in reference structures which possess a maximum and minimum value for that number of atoms. Therefore, the Kappa 1 shows the degree of complexity of a binding pattern. The Kappa 2 indicates the degree of linearity or star-likeness of bonding patterns. The Kappa 3 indicates the degree of branching at the center of a molecule. More details about topological indices can be found elsewhere.

### 4.1.1.3 Electronic Properties

Electronic properties of molecule can be described by a wide variety of different parameters such as the Hammett electronic constant ( $\sigma$ ), the partial atomic charges, dipole moments ( $\mu$ ) and frontier molecular orbital energies.

The Hammett electronic constant ( $\sigma$ ) was the first parameter used to describe electronic effects. However, it could account for only substituents on an aromatic ring. This disadvantage limits its use. Therefore, many new electronic parameters have been applied in the QSAR study, such as the partial atomic charges which are electronic charges of each atom in a molecule and are important descriptors for drug design. ${ }^{56}$ The partial atomic charges can be calculated by quantum chemical wave functions. ${ }^{57,58}$ Wave functions either can be obtained using ab initio methods depending on the requested accuracy of the wave function and also on the available computational resources. ${ }^{59}$ The molecular dipole moment is the dipole moment of the molecule taken as a whole. Dipole moment was calculated by using partial charge
information. The molecular dipole moment is a good indicator of the overall polarity of a molecule. Its value is equal to the vector sum of the individual bond dipole moments. This vector sum reflects both magnitude and direction of each individual bond dipole moment. ${ }^{60}$ The individual bond dipole moment ( $\mu$ ), is defined as equation (4.5):

$$
\begin{equation*}
\mu=4.8 \times \delta \times d \tag{4.5}
\end{equation*}
$$

where 4.8 represent the charge on an electron, $\delta$ is the amount of charge separation on the two atoms, and d is the bond length.

The electronic properties of various substituents clearly have an effect on a drug's ionization or polarity. This in turn may have an effect on how easily a drug can pass through cell membranes or how strongly it can bind to a receptor. Moreover, parameters derived from quantum chemical calculation, e.g., orbital energies and partial atomic charges are important electronic descriptor in the frontier molecular orbitals. Two specific frontier molecular orbitals of particular interest in drug-receptor interaction are the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO). The HOMO energy is roughly related to the ionization potential of a molecule, while the LUMO energy is related to the electron affinity. The magnitudes of these quantities are measures of the overall susceptibility of the molecule to losing a pair of electrons to an electrophile or accepting a pair of electrons from a nucleophile.

### 4.12 Statistical Analysis for QSAR Study

After the desired physicochemical properties were calculated, the next step is to find relation with the biological activity in a quantitative manner. For this purpose, a statistical analysis is needed. The regression analysis is one of the most frequently used statistical analyses to find a correlation equation. The general form of multiple linear regression (MLR) models is depicted in equation (4.6). The assumption in regression analysis is that independent X variables, e.g., physicochemical properties, can be measured or determined more precisely than the dependent Y variables, e.g., biological activity. This is usually hold true for the recent QSAR studies because most of physicochemical properties can be calculated at a very high accuracy, hence with relatively much smaller error than that of the biological data, especially if the biological response is from an in vivo assay.

$$
\begin{equation*}
y=\beta_{0}+\beta_{1} x_{1}+\beta_{2} x_{2}+\ldots+\beta_{m} x_{m} \tag{4.6}
\end{equation*}
$$

where $\mathrm{y}=$ dependent variable
$\mathrm{x}_{1}, \mathrm{x}_{2}, \mathrm{x}_{3}, \ldots=$ independent variables
$\beta_{0}, \beta_{1}, \beta_{2}, \ldots=$ regression coefficients
One of the goals in QSAR studies is the ability to describe a biological activity of a compound from its physicochemical properties, it is important to achieve this ability by using a statistical analysis method that can minimize an error between actual and calculated biological values ( $\varepsilon$ ). Therefore, a least-squares method, which has a strategy to minimize the residual sum of squares (sum of squares of the errors), is usually employed. Considering the simplest linear regression equation (equations 4.7 and 4.8) of n chemical compounds, a model with only one X variable, the regression coefficients could be evaluated as following.

$$
\begin{align*}
& y_{\text {obs }}=\beta_{0}+\beta_{1} x+\varepsilon  \tag{4.7}\\
& y_{\text {cal }}=\beta_{0}+\beta_{1} x \tag{4.8}
\end{align*}
$$

First, since the $\Sigma \varepsilon^{2}=\Sigma \Delta^{2}=\Sigma\left(y_{\text {obs }}-y_{c a l}\right)^{2}$ shall be a minimum, the derivative of the function $\mathrm{f}=\Sigma\left(\mathrm{y}_{\text {obs }}-\beta_{0}-\beta_{1} \mathrm{x}\right)^{2}$ with respect to $\beta_{0}$ and $\beta_{1}$ are set to zero, i.e., $\mathrm{df} / \mathrm{d} \beta_{0}=$ $\mathrm{df} / \mathrm{d} \beta_{1}=0$ (equations 4.9 and 4.10 ).

$$
\begin{align*}
& \mathrm{df} / \mathrm{d} \beta_{0}=2 \cdot \Sigma\left(y-\beta_{0}-\beta_{1} x\right) \cdot(-1)=0  \tag{4.9}\\
& d f / d \beta_{1}=2 \cdot \Sigma\left(y-\beta_{0}-\beta_{1} x\right) \cdot(-x)=0 \tag{4.10}
\end{align*}
$$

Second, the so-called normal equations (4.11) and (4.12) are then resulted from equations (4.9) and (4.10).

$$
\begin{equation*}
6619-\Sigma y=n \beta_{0}+\beta_{1} \Sigma x d ? 𠃌 \delta \tag{4.11}
\end{equation*}
$$

Finally, the regression coefficients $\beta_{0}$ and $\beta_{1}$ (equations 4.13 and 4.14 ) could be obtained by mathematical solving of the equations (4.11) and (4.12).

$$
\begin{align*}
& \beta_{1}=\frac{\mathrm{n} \Sigma(\mathrm{xy})-(\Sigma \mathrm{x}) \cdot(\Sigma \mathrm{y})}{\mathrm{n} \Sigma\left(\mathrm{x}^{2}\right)-(\Sigma \mathrm{x})^{2}}  \tag{4.15}\\
& \beta_{0}=\bar{y}-\beta_{1} \bar{x} \tag{4.16}
\end{align*}
$$

where $\bar{y}=$ mean of y variable
$\bar{x}=$ mean of x variable
For the multiple linear regression equation (equation 4.6), a model with more than one X variables, the regression coefficients could be evaluated in the same manner. At this point it is necessary to have some indicators to justify the significance and quality of the correlation equations. The first indicator is the standard deviation, s , which is based on variance. It is defined as a sum of squared errors (SSE) per degree of freedom (DF) in a calculation (equation 4.15). The DF is calculated from n-k-1, where n is the number of compounds and k is the number of variables used in the equation. The lower the $s$ value, the better is the regression model. This is because SSE is the variation that could not be explained by the regression equation. Another variation, sum of squared regression (SSR), is the variation that could be explained by the regression equation. Summation of the above two variances gives the total variance (sum of squared total, SST). The calculations of these three values are illustrated in equations (4.15) to (4.18).

$$
\begin{gather*}
\mathrm{S}=\mathrm{SSE} /(\mathrm{n}-\mathrm{k}-1)  \tag{4.15}\\
\mathrm{SSE}=\Sigma \varepsilon^{2}=\Sigma\left(\mathrm{y}_{\text {observe }}-\mathrm{y}_{\text {calculate }}\right)^{2}  \tag{4.16}\\
\mathrm{SSR}=\Sigma\left(\mathrm{y}_{\text {calculate }}-\mathrm{y}_{\text {mean }}\right)^{2}  \tag{4.17}\\
\mathrm{SST}=\mathrm{SSR}+\mathrm{SSE}=\Sigma\left(\mathrm{y}_{\text {observe }}-\mathrm{y}_{\text {mean }}\right)^{2}=\Sigma \mathrm{y}^{2}-(\Sigma \mathrm{y})^{2} / \mathrm{n} \tag{4.18}
\end{gather*}
$$

The second and most popular indicator used to measure the quality of the QSAR model is the Pearson correlation coefficient, $r$ (equation 4.19). The $r$ statistics has a value between -1 and $1(-1 \leq \mathrm{r} \leq 1)$, where $\mathrm{r}=1$ implies a perfect positive correlation, $r=-1$ implies a perfect negative correlation, and $r=0$ implies no correlation. Therefore, a value of r close to 1 or -1 indicates a strong degree of linear relationship.

$$
\begin{equation*}
\mathrm{r}=\frac{\Sigma(\mathrm{xy})-(\Sigma \mathrm{x}) \cdot(\Sigma \mathrm{y}) / \mathrm{n}}{\sqrt{\Sigma\left(\mathrm{x}^{2}\right)-(\Sigma \mathrm{x})^{2} / \mathrm{n}} \cdot \sqrt{\Sigma\left(\mathrm{y}^{2}\right)-(\Sigma \mathrm{y})^{2} / \mathrm{n}}} \tag{4.19}
\end{equation*}
$$

Generally, $r^{2}$ is used instead of the $r$ itself, thus $0 \leq r^{2} \leq 1$. The $r^{2}$ statistics is a ratio of the variance explained by the regression model to the total variance (equation 4.20). Therefore, it gives an information on how many percentage of the variation in
the biological activity (Y variable) can be explained by the physicochemical properties ( X variables) presented in the equation. For example, in case of the sum of squared error (SSE, $\Sigma \varepsilon^{2}$ ) goes to zero, $\mathrm{r}^{2}$ goes to 1 . Then, the equation can explain all $100 \%$ of the variation in the biological activity.

$$
\begin{align*}
\mathrm{r}^{2} & =\Sigma\left(\mathrm{y}_{\text {calculate }}-\mathrm{y}_{\text {mean }}\right)^{2} / \Sigma\left(\mathrm{y}_{\text {observe }}-\mathrm{y}_{\text {mean }}\right)^{2} \\
& =\mathrm{SSR} / \mathrm{SST}=1-\mathrm{SSE} / \mathrm{SST} \tag{4.20}
\end{align*}
$$

The third indicator is the F value, which measures the level of statistical significance of the regression model. The F value can be calculated from the equation (4.21). In this case, the number of variables being included to derive the model has a stronger influence than that of the standard deviation. Only F values being larger than the $95 \%$ significance limit prove the overall significance of a regression equation. With the same n and k values, the higher the F value is, the higher is the overall significance level of the model.

$$
\begin{equation*}
\mathrm{F}=\frac{\mathrm{r}^{2} \cdot(\mathrm{n}-\mathrm{k}-1)}{\mathrm{k} \cdot\left(1-\mathrm{r}^{2}\right)} \tag{4.21}
\end{equation*}
$$

In general, the regression equation can be accepted in QSAR studies if the following four criteria are met. Firstly, the correlation coefficient $r$ is around or better than $0.8\left(r^{2} \geq 0.64\right)$ for in vivo data or $0.9\left(r^{2} \geq 0.81\right)$ for in vitro data. ${ }^{62}$ Secondly, the standard deviation s is not much larger than the standard deviation of the biological data. Thirdly, the overall significance level is better than $95 \%$ as indicated by the F value. Fourthly, the confidence intervals of all individual regression coefficients prove that they are justified at the $95 \%$ significance level, i.e., their confidence intervals are smaller than the absolute values of the regression coefficients. In addition, there should be no fewer than five compounds for each chemical descriptor used in the final equation ( $n>5 k$ ) to prevent the chance correlations. Moreover, the descriptors should not be intercorrelated, i.e., interdescriptor correlation coefficients should be less than $0.6 .{ }^{63}$

Using the $r^{2}$ alone to justify the QSAR model is not recommended. But the predictability of the model should also be considered. This is because the $r^{2}$ gives information only on the reproducibility, how well the model reproduces the biological
activity of the compounds included in the model, not the predictability. The predictability, an ability to predict a biological activity of a new compound outside the model, could be measured by various approaches, e.g., cross-validation, ${ }^{64}$ bootstrapping, random change of the values of the dependent variable, and dividing the original set into training and testing sets. However, the most widely used method is the cross-validation. In this method, the predictability of the model is estimated by repeatedly leaving out one (or more) compound(s) at a time until each compound is excluded exactly once. Using the reduced set of data, the model is derived and is used to predict the activity of the left out compound. During the cross-validation test, the sum of the squared prediction errors called the predictive residual sum of squares (PRESS), the cross-validated correlation coefficient ( $\mathrm{r}_{\mathrm{cv}}^{2}$ or $\mathrm{q}^{2}$ ), and the crossvalidated standard error of estimate ( $\mathrm{s}_{\mathrm{cv}}$ ) are evaluated. These values are calculated in the same manner as SSE, $\mathrm{r}^{2}$, and s , respectively (shown in equations 4.22 to 4.24). A smaller $\mathrm{s}_{\mathrm{cv}}$ and a larger $\mathrm{q}^{2}$ indicate the model's good predictability. Generally, a model with the $\mathrm{q}^{2}$ value of greater than 0.50 is accepted as a good model. ${ }^{65}$

$$
\begin{align*}
\text { PRESS } & =\Sigma\left(\text { yobserved }-y_{\text {predicted }}\right)^{2}  \tag{4.22}\\
q^{2} & =1-\text { PRESS } / \text { SST }  \tag{4.23}\\
s_{c v} & =(\text { PRESS } / n)^{1 / 2} \tag{4.24}
\end{align*}
$$

The main goal for QSAR study is the ability to predict biological activity of other compounds outside the model rather than the ability to reproduce the biological activity of the compounds included in the model. Therefore, we should test the model by predicting the activity of the "new compound", which is not included in the process of deriving the model. Therefore, the real predictive ability of the model could not be determined by the $\mathrm{q}^{2}$ value. In order to investigate the real predictive ability, the compounds are randomly divided into 2 sets, training set and testing set. Compounds in the training set are used to derive the model. Subsequently, the obtained model is used to predict the biological activity of compounds in the testing set. By comparing between predicted and actual values, the real predictive power is obtained.

The overall steps of QSAR analysis in this study are summarized in Figure 4.1.

Figure 4.1 Flow chart of the QSAR methodology in this study.

### 4.2 Calculations of Properties

There are a lot of parameters that can be used in the field of QSAR study. Totally 58 physicochemical parameters were calculated using TSAR ${ }^{57}$ and Gaussian 98 softwares. ${ }^{46}$ These parameters can be grouped into three classes: hydrophobic, steric and electronic properties.

### 4.2.1 Hydrophobicity properties

For the hydrophobicity parameter, the $\log \mathrm{P}$ was calculated using the TSAR software.

### 4.2.2. Steric properties

Structural parameters, 9 bond lengths (R), 10 bond angles (A), and 12 torsion angles (T), were taken from the HF/3-21G optimized structures. In order to represent these parameters, the atom number corresponding to the structure of tricyclic 1,2,4trioxane in Figure 3.1 (Chapter 3) was given in the parenthesis. For example, the R(12) parameter represents the bond length between atom 1 and 2 , the $A(1-2-3)$ means the bond angle between atom 1,2 , and 3 , and the $T(1-2-3-4)$ is the torsion angle between atom 1, 2, 3, and 4. All-structural parameters are as follows $-\mathrm{R}(1-2), \mathrm{R}(2-$ 3), $R(3-4), R(4-5), R(3-13), R(12-13), R(8 a-12 a), R(8-8 a), R(12 a-12), A(4-5-5 a)$, $\mathrm{A}(3-4-5), \mathrm{A}(13-3-4), \mathrm{A}(12-13-3), \quad \mathrm{A}(8 \mathrm{a}-12 \mathrm{a}-5 \mathrm{a}), \quad \mathrm{A}(2-3-4), \mathrm{T}(4-5-5 \mathrm{a}-12 \mathrm{a}), \mathrm{T}(3-$ $4-5-5 a), \quad \mathrm{T}(13-3-4-5), \mathrm{T}(12-13-3-4), \mathrm{T}(2-3-4-5), \mathrm{T}(8-8 \mathrm{a}-12 \mathrm{a}-5 \mathrm{a}), \mathrm{T}(1-2-3-13), \mathrm{T}(3-2-$ $1-12 a), T(1-12 a-12-13), T(12 a-12-13-3), T(12-13-3-2)$ and $T(4-3-2-1)$.

The molar refractivity (MR) was calculated using the TSAR software. Topological index after the Balaban method ${ }^{66}$ and the following 6 connectivity indices were calculated using the TSAR software-Chi0 (atoms), ChiV0 (atoms), Chi1 (bonds), ChiV1 (bonds), Chi2 (path), and ChiV2 (path). In addition, three shape indices, i.e., Kappa 1, Kappa 2, and Kappa 3, were also computed.

### 4.2.3. Electronic properties

For the electronic parameters, atomic charges obtained by the Mulliken Population Analysis (MPA) method in the Gaussian98 software were used. Atomic charges of 13 atoms namely $\mathrm{O}_{1}, \mathrm{O}_{2}, \mathrm{C}_{3}, \mathrm{C}_{4}, \mathrm{C}_{5}, \mathrm{C}_{5 \mathrm{a}}, \mathrm{C}_{6}, \mathrm{C}_{7}, \mathrm{C}_{8}, \mathrm{C}_{8 \mathrm{a}}, \mathrm{C}_{12}, \mathrm{C}_{12 \mathrm{a}}$ and $\mathrm{O}_{13}$ were computed at the HF/6-31G(d) level.

Dipole moment, HOMO energy, and LUMO energy were also calculated at the HF/6-31G(d) level.

### 4.3 Results and Discussions

All the calculated physicochemical properties were related to the antimalarial activity by the multiple linear regression analysis using the stepwise procedure. The methodology of the stepwise method is to start with the best single variable to build the model and then add further significant variables, according to their contribution to the model. During the process, there is a proof whether already introduced variables are no longer significant at a later stage. If it is, this variable is excluded from the equation. The adding and proofing process continues until a static model is reached.

In order to access the real predictive ability, 32 compounds were divided into the training set (85\%) and testing set (15\%). Therefore, four compounds were randomly selected for the testing set, i.e., compound number $15,20,23$ and 28 and the remaining 28 compounds, the training set, were used to derive the model. Four parameters were statistically selected into the model (equation 4.25).

$$
\begin{align*}
& \text { Activity }=-\mathbf{0 . 4 3 4} * \mathrm{~A}(\mathbf{1 3 - 3 - 4})-\mathbf{0 . 1 1 4} * \mathrm{~T}(\mathbf{1}-\mathbf{2}-3-13)+\mathbf{4 . 6 3 2}\left(\mathrm{C}_{\mathbf{8 a}} \text { charge }\right) \\
&+\mathbf{0 . 5 0 4}\left(\mathbf{C}_{\mathbf{1 2}} \text { charge }\right)+\mathbf{6 4 . 5 1 8}  \tag{4.25}\\
& \mathrm{n}=28, \mathrm{r}^{2}=0.735, \mathrm{q}^{2}=0.470, \mathrm{~S}=0.235, \mathrm{~F}=15.921
\end{align*}
$$

QSAR model in equation (4.27), has a correlation coefficient ( $\mathrm{r}^{2}$ ) 0.735 and a cross-validated correlation coefficient $\left(q^{2}\right) 0.470$. Both values are lower than the acceptable value of 0.81 and 0.50 , respectively. ${ }^{62,65}$ Thus, the improvement of the $q^{2}$ and $r^{2}$ values could be attained by omitting some compounds with high residual values, i.e., compounds 22, 2 and 11 (Table 4.1). The best QSAR model was then obtained as shown in equation (4.26).

$$
\begin{align*}
\text { Activity }= & -0.397^{*} A(13-3-4)-0.138 * T(1-2-3-13)+4.211\left(\mathrm{C}_{8 \mathrm{a}} \text { charge }\right) \\
& +0.644^{*}\left(\mathrm{C}_{12} \text { charge }\right)+61.998 \tag{4.26}
\end{align*}
$$

$\mathrm{n}=25, \mathrm{r}^{2}=0.832, \mathrm{q}^{2}=0.697, \mathrm{~S}=0.174, \mathrm{~F}=24.776$

The $r^{2}(0.832)$ and $q^{2}(0.697)$ values of equation (4.26) are quite good, i.e., both values are higher than the acceptable values. ${ }^{62,65}$ The correlation coefficients between each pair of variables were calculated (see Table 4.1) and the $\mathrm{C}_{8 \mathrm{a}}$ charge parameter
was found to have the highest relationship with activity. Moreover, all the interdescriptor correlation coefficients are less than 0.6 , which indicates no intercorrelation between each pair of variables in the model, hence, model 2 (equation 4.26 ) is an acceptable model. ${ }^{63}$

Table 4.1 Predicted activities and residuals of 28 compounds in the training set by the QSAR model (eg. 4.25).

| Compound No. | Actual Activity | Predicted Activity | Residual |
| :---: | :---: | :---: | :---: |
| 1 | 6.718 | 6.543 | 0.175 |
| 2 | 6.796 | $\begin{array}{r}6.5 \\ \hline \quad 7.207\end{array}$ | -0.411 |
| 3 | 6.959 | 7.166 | -0.207 |
| 4 | 6.998 | 6.936 | 0.062 |
| 5 | 7.090 | 7.328 | -0.238 |
| 6 | 7.182 | 7.229 | -0.047 |
| 7 | 7.198 | 7.175 | 0.023 |
| 8 | 7.215 | 7.339 | -0.124 |
| 9 | 7.279 | 7.305 | -0.026 |
| 10 | 7.342 | 7.328 | 0.014 |
| 11 | 7.391 | 7.009 | 0.382 |
| 12 | 7.445 | 7.273 | 0.172 |
| 13 | 7.561 | 7.328 | 0.233 |

|  | Activity | $\mathrm{A}(13-3-4)$ | $\mathrm{T}(1-2-3-13)$ | $\mathrm{C}_{8 \mathrm{a}}$ charge | $\mathrm{C}_{12}$ charge |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Activity | 1 | -0.226 | -0.147 | 0.722 | 0.294 |
| $\mathrm{~A}(13-3-4)$ | -0.226 | 1 | -0.066 | 0.237 | 0.249 |
| $\mathrm{~T}(1-2-3-13)$ | -0.147 | -0.066 | 1 | 0.067 | 0.534 |
| $\mathrm{C}_{8 \mathrm{a}}$ charge | 0.722 | 0.237 | 0.067 | 1 | 0.360 |
| $\mathrm{C}_{12}$ charge | 0.294 | 0.249 | 0.534 | 0.360 | 1 |

In QSAR study, the activity depends on all the variables presented in the model, therefore, using only one variable to predict the activity is not appropriate and it may not give a proper activity value. However, the analysis on each individual variable alone (assuming that the other variables are constant) could give useful information in a qualitative manner, which is very helpful for the design of new more effective drugs. Therefore, we performed the analysis for all parameters in this study.

The $\mathrm{O}_{13}-\mathrm{C}_{3}-\mathrm{C}_{4}$ angle, $\mathrm{A}(13-3-4)$ (see Figure 3.1) is involved in the structural change during the $\mathrm{C}_{3}-\mathrm{C}_{4}$ bond breaking step in the reaction mechanisms (see Figure 6.1 in Chapter 6). Therefore, it has relationship with the activity and is presented in the model. Compound with smaller A(13-3-4) has higher activity as indicated by a minus sign in the equation. It can be seen that compounds having substituent group at the $C_{3}$ position ( $\mathrm{R}_{1}$ ), e.g., compounds $1,4,7,12$ and 13 , the smaller of the angle $\mathrm{A}(13-3-4)$, the higher of the activity (see table 4.3). This may be explained by the facts that compound with smaller angle has more strain in the ring systems and so it is easier to achieve this structural change.

Table 4.3 Relationship between the angle of $\mathrm{O}_{13}-\mathrm{C}_{3}-\mathrm{C}_{4}, \mathrm{~A}(13-3-4)$ and activity

| Compound | $\mathrm{A}(13-3-4)$ | Activity |
| :---: | :---: | :---: |
| 1 | $112.1^{0}$ | 6.718 |
| 4 | $110.6^{0}$ | 6.998 |
| 7 | $110.0^{0}$ | 7.198 |
| 12 | $109.8^{0}$ | 7.445 |
| 13 | $109.7^{0}$ | 7.531 |

The torsion angle $T(1-2-3-13)$ is involve to substituted carbon atoms ( $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ ) and oxygen atoms of peroxide linkage. A minus sign of this torsion parameter refers that compound with smaller $\mathrm{T}(1-2-3-13)$ value has higher activity. This is because compounds with smaller $\mathrm{T}(1-2-3-13)$ value is easier to proceed the structural change during the reaction mechanism in which the oxygen-free radical is moved away from the ring after the attack of Fe at oxygen atom of the peroxide linkage. For example, compounds $2,6,8,28,30$ and 32 have torsion angle $T(1-2-3-13) 73.8^{0}$, $73.6^{0}, 73.4^{0}, 72.8^{0}, 72.3^{0}$ and $71.4^{0}$ and activity 6.796, 7.182, 7.215, 7.822, 8.050 and 8.081, respectively, it is clearly that the larger of torsion angle $\mathrm{T}(1-2-3-13)$ the lower of the activity (see table 4.4).

Table 4.4 Relationship between the torsion angle $\mathrm{T}(1-2-3-13)$ and activity.

| Compound | $\mathrm{T}(1-2-3-13)$ | Activity |
| :---: | :---: | :---: |
| 2 | $73.8^{0}$ | 6.796 |
| 6 | $73.6^{0}$ | 7.182 |
| 8 | $73.4^{0}$ | 7.215 |
| 28 | $72.8^{0}$ | 7.822 |
| 30 | $72.3^{0}$ | 8.050 |
| 32 | $71.4^{0}$ | 8.081 |

$\mathrm{C}_{8 \mathrm{a}}$ atomic charge has the highest correlation coefficient $(\mathrm{r}=0.722)$ as shown in Table 4.2. Therefore, this parameter has more contribution to activity than others that described in the model but rather to compounds $25-32$ only because such compounds have substituents at $\mathrm{C}_{8 \text { a }}$ position $\left(\mathrm{R}_{3}\right)$. Atomic charges of $\mathrm{C}_{8 \mathrm{a}}$ in those compounds show significantly different from the rest, e.g. compounds 25-32 have $\mathrm{C}_{8 \mathrm{a}}$ atomic charge in the range of -0.164 to -0.179 , while compound 1-24 have $\mathrm{C}_{8 \mathrm{a}}$ atomic charge in the range of -0.318 to -0.335 . A positive coefficient of $\mathrm{C}_{8 \mathrm{a}}$ parameter in the model indicates that compound with less negative $\mathrm{C}_{8 \mathrm{a}}$ are design to have higher activity. This is confirmed by our results as shown in the table 4.5, i.e. compound 31 has the less negative charge and hence the highest activity.

Table 4.5 Relationship between the $\mathrm{C}_{8 \mathrm{a}}$ atomic charge and activity.

| Compound | C $_{8 \mathrm{a}}$ charge | Activity |
| :---: | :---: | :---: |
| 23 | -0.318 | 6.575 |
| 25 | -0.177 | 7.445 |
| 28 | -0.175 | 7.822 |
| 32 | -0.172 | 8.081 |
| 31 | -0.164 | 8.097 |

From Appendix A, it is clear that the substituent $R_{3}$ influence the charge of O-atom of peroxide linkage, these compounds with $\mathrm{R}_{3}$ at $\mathrm{C}_{8 \mathrm{a}}$ position has $\mathrm{O}_{1}$ charge more negative than $\mathrm{O}_{2}$ charge whereas the compounds without substituent at $\mathrm{C}_{8 \mathrm{a}}$ position show the opposite results. This suggest that compounds 25-32 should follow the pathway B of the reaction mechanism with $\mathrm{Fe}^{2+}$ bind to $\mathrm{O}_{2}$ and follow by $\mathrm{C}_{3}-\mathrm{C}_{4}$ bond cleavage to from $\mathrm{C}_{4}$ radical (see in Figure 6.1). This results also agree well with our the docking results (Chapter 6).

Similarly, $\mathrm{C}_{12}$ atomic charge will describe better for compounds having substituents at $\mathrm{C}_{12}$ than others. A plus sign in the model implies that compound with more positive $\mathrm{C}_{12}$ charge will have higher antimalarial potency. As shown in table 4.6 compound 31 has the highest positive charge on $\mathrm{C}_{12}$ atom and therefore the greatest activity. Having substituents at $\mathrm{C}_{12}$ position $\left(\mathrm{R}_{4}\right)$ also leads to a different charge of carbon atoms in ring $C$ of compounds $16-21$, i.e., $C_{6}(-0.336$ to -0.354$), C_{7}(-0.316$ to $-0.318)$, and $C_{8}(-0.336$ to -0.344$)$ compare to compounds without substituents at $C_{12}$ position $\left(\mathrm{R}_{4}\right)$ which have $\mathrm{C}_{6}(-0.317$ to -0.319$), \mathrm{C}_{7}(-0.319$ to -0.324$)$, and $\mathrm{C}_{8}(-0.318$ to -0.330 ). This indicates that ring C is important feature of structure requirements in the reaction mechanism for the inhibition.

Table 4.6 Relationship between the $\mathrm{C}_{12}$ atomic charge and activity.

| acompound 9 Activity |  |  |
| :---: | :---: | :---: | :---: |
| 4 | 0.574 | 6.998 |
| 9 | 0.575 | 7.279 |

### 4.4 QSAR Summary

The relationship between antimalarial activities and molecular properties of tricyclic 1,2,4-trioxane compounds were investigated by QSAR technique. From the statistical analysis obtained for 28 compounds in training set, both $\mathrm{r}^{2}(0.735)$ and $\mathrm{q}^{2}(0.470)$ values are below the acceptable value. Statistically better model could be attained by omitting some compounds with high residual values, i.e., compounds 22 , 2, 11 were omitted. The best QSAR model for 25 compounds was obtained with $r^{2}(0.832)$ and $q^{2}(0.697)$. Four parameters are the angle $\bar{A}(13-3-4)$, torsion angle $T(1-2-$ $3-13), C_{8 a}$ and $C_{12}$ atomic charges were statistically selected into the model and all the interdescriptor correlation coefficients are less than 0.6, which indicates no intercorrelation between each pair of variables in the model, hence, the model is acceptable model. The best QSAR model were obtained indicates compound with smaller angle $\mathrm{A}(13-3-4)$, smaller $\mathrm{T}(1-2-3-13)$, more positive $\mathrm{C}_{8 \mathrm{a}}$ and $\mathrm{C}_{12}$ charges values have higher activities.

Finally, the real predictive ability of the best QSAR model was judged by comparison between actual and predicted activities of compounds in the testing set. The obtained models can predict the activities very close to the experimental values. thus confirming their reliability.

## CHAPTER 5

## THREE DIMENSIONAL QUANTITATIVE STRUCTURE ACTIVITY RELATIONSHIP (3D-QSAR)

In classical QSAR study, most of physicochemical properties used do not represent three dimensional structure of compound directly. In reality, stereochemistry of a drug play an important role to its biological activity because drug's binding site is a chiral environment and performs discrimination between different enantiomers of an optically active drug. Drug must have a three dimensional structure complementary to its binding site to exert high affinity with the target which may result in high activity. Therefore, three-dimensional quantitative structure activity (3D-QSAR) approaches are very useful and plays an important role in drug design and development process. Several approaches to 3D-QSAR have been developed, e.g., Comparative Molecular Field Analysis (CoMFA). ${ }^{67}$ These techniques are usually employed in drug discovery to find the common features that are important in binding to the biologically relevant target. They are based on the assumption that changes in binding affinities of ligands are related to changes in different fields surrounding the molecules. The 3D-QSAR models are usually generated by multivariate statistics using the Partial Least Squares (PLS) analysis ${ }^{68}$ and can be used for predicting the binding affinity of new molecules.

In this study, the CoMFA technique was selected for 3D-QSAR study of tricyclic 124. Hoxamenamagex บันวิทยบริการ

จุฬาลงกรณ์มหาวิทยาลัย

### 5.1 Theoretical Background of CoMFA

Comparative molecular field analysis (CoMFA) is one of the most powerful 3D-QSAR techniques providing further insight into relationships between structure and function of drug. This methodology is based on assumption that non-covalent forces dominate receptor-drug interactions and that these forces can be described in terms of steric and electrostatic fields. The changes in biological activities of binding affinities of sample compounds correlate with changes in steric and electrostatic fields around these molecules. Practically, there are 4 main steps in CoMFA study: alignment, interaction energy calculation, statistical analysis, and interpretation. Detail for each steps are discussed as following.

### 5.1.1 Alignment Rule

An alignment of molecules is the most important input variable in CoMFA study since relative interaction energies depend strongly on relative molecular positions. The rationale for proper alignment is that differences in field values at each lattice point should reflect differences in structure only, not chance variations on model geometry. Three general methods used in molecular alignment are 1) alignment based on pharmacophore, this method assumes that all molecules that have activity at the same target must present their pharmacophoric groups in the same configuration in space. Then, one can search the conformational space of all molecules to identify a convergent distance map which defines the phamacophore geometry common to all molecule. This method is particularly useful when the molecules to be analyzed represent a diverse set of structures rather than homologous series. 2) Minimization of root mean square (rms) distance between specified pairs of atoms, when aligned with this method, field differences are due to differences in functionality than to conformational variations. 3) Field fit, this method aligns a molecule so as to minimize the differences between its field values at a lattice point and those of some template field.

### 5.1.2 Interaction Energy Calculation

To calculate the electrostatic interaction, partial atomic charges were obtained from GAUSSIAN98. A grid spacing of $2 \AA$ was used to generate a cubic lattice around
all molecules based on the molecular volume of the structures. Three dimensions ensured that the grid extended beyond the molecular size by $4 \AA$ in all directions. Molecular interactions between probe atom and aligned molecules were then calculated. A sp ${ }^{3}$ carbon probe atom was placed at each lattice point, and the interactions of the steric and electrostatic fields with each atom in molecule were all calculated with CoMFA standard scaling and then put in a CoMFA QSAR table. The minimum sigma value was set to 2.0 $\mathrm{kcal} / \mathrm{mol}$ and energy cutoff values of $30 \mathrm{kcal} / \mathrm{mol}$ were selected for both electrostatic and steric fields.

## Steric Field

Steric interactions are calculated from the van der Waals potential functions using the Lennard-Jones 12-6 function, which can be described in the form below:

$$
E_{\text {vanderWaals }}=\sum_{\mathrm{i}, \mathrm{j}}\left[\frac{A_{\mathrm{ij}}}{\mathrm{r}_{\mathrm{ij}}^{12}}-\frac{B_{\mathrm{ij}}}{r_{\mathrm{ij}}^{6}}\right]
$$

where $A_{i j}$ is a coefficient depicting repulsive heteroatomic interaction with hydrogen $\left(\left(\mathrm{A}_{\mathrm{i}} \mathrm{A}_{\mathrm{j}}\right)^{1 / 2}\right)$.
$\mathrm{B}_{\mathrm{ij}}$ is a coefficient depicting attractive heteroatomic interaction with hydrogen $\left(\left(\mathrm{B}_{\mathrm{i}} \mathrm{B}_{\mathrm{j}}\right)^{1 / 2}\right)$.
$r_{i j}$ is a distance between atom i of drug molecule and probe atom $\mathrm{j}(\AA)$.

## Electrostatic Field

Electrostatic interactions are calculated from the Coulomb potential using a charge probe atom. Electrostatic properties of molecules are typically described by point charges at the center of atoms. The general form of electrostatic interaction between two molecules is given by

$$
E_{\text {ele }}=\sum_{i, j}\left[\frac{q_{i} q_{j}}{r_{i j}}\right]
$$

where $q_{i}, q_{j}$ are atomic net charges of atom i of drug molecule and of probe
atom j , respectively.
$\mathrm{r}_{\mathrm{ij}}$
is a distance between atom i of drug molecule and probe atom $j(\AA)$.

### 5.1.3 Statistical Analysis using Partial Least-Squares Method

A typical CoMFA data table usually contains hundreds or thousands of columns of interaction energy values and a number of compound included in the study is relatively much smaller than the number of the energy columns. Thus, a mathematical difficulty arises because of a large number of descriptors. For this reason, the multiple linear regression technique can not be used directly without the danger of chance correlation. Partial Least Square (PLS) was developed for such problems. ${ }^{68}$ Not only it can be applied to solve an equation having hundreds or thousands of variables while involving only a small number of biological data, but also it can be simultaneously handled to derive models. In this latter case, some missing values can be handled without any problem. PLS is an iterative procedure which applies two criteria to produce its solution. First, for each iteration to generate a better set of coefficients (extract a new component), the criterion is to maximize the degree of commonality between all of the structural parameter columns collectively and the experimental data. Second, during the evaluation phase of the PLS iteration, the criterion for acceptance of the principal component just generated (and subsequent components as well) is the incremental improvement in the ability to predict, not to reproduce, the biological data.

The technique used in PLS to assess predictive ability of a QSAR model is crossvalidation. Cross-validation, ${ }^{69}$ also known as leave one out, rests on the intuitively satisfying, though more computationally demanding, concept that the best way to assess predictive performance is to do some predictions. The process of cross-validation is shown in Figure 5.1. In cross-validating, one pretends that one or more of the known experimental values is in fact unknown. The analysis being cross-validated is repeated, excluding the temporarily unknown compounds from the very beginning. The resulting equation is used to predict the experimental measurement for the omitted compounds, and the resulting individual squared errors of the prediction are accumulated. The crossvalidation is the sum of the squared prediction errors, called the PRESS (Predictive

Residual Sum of Squares). For evaluation of the overall analysis, the PRESS is commonly expressed as a cross-validation $r^{2}\left(q^{2}\right)$ value.

Figure 5.1 Cross-validate procedure. ${ }^{69}$

The general form of the equation is;

$$
\text { Activity }=\mathrm{C}+\Sigma \Sigma \mathrm{c}_{\mathrm{ij}} \mathrm{~S}_{\mathrm{ij}}
$$

Where $\mathrm{S}_{\mathrm{ij}}$ is the column in the matrix that corresponds to placing probe group j at grid point $\mathrm{i}, \mathrm{c}_{\mathrm{ij}}$ is the coefficient for each column, and C is the sum of the deviations of the observation from the fitted equation.

The PLS method expresses a dependent variable (y) in term of linear combination of the original independent ( x ) variables as the following

$$
\begin{aligned}
y & =b_{1} t_{1}+b_{2} t_{2}+b_{3} t_{3}+. . b_{m} t_{m} \\
\text { where } t_{1} & =c_{11} x_{1}+c_{12} x_{2}+c_{1 p} x_{p} \\
t_{2} & =c_{21} x_{1}+c_{22} x_{2}+c_{2 p} x_{p} \\
t_{m} & =c_{\mathrm{m} 1} x_{1}+c_{m 2} x_{2}+c_{m p} x_{p}
\end{aligned}
$$

where $t_{1}, t_{2}$ etc. are called latent variables (or components) and are constructed in such a way that they form an orthogonal set. The maximum number of latent variables ( m ) is the smaller value between the number of x values or the number of molecules. However, there is an optimum number of latent variables in the model beyond which the predictive ability of the model does not increase. A PLS model is often evaluated according to its ability to predict the activity of compounds not used to derive the model. PLS generates iteratively one component at a time by maximizing the degree of commonality between all of the descriptor variables collectively and the biological data. The process stops when the requested number of components is extracted. The number of significant PLS component (latent variables) is determined by cross-validation test. Usually a model with less than the maximum number of components gives a better cross-validated sum of squared residuals than the full model. The model with optimal number of components has a higher standard error of fit than a full-rank model, but it is generally more reliable for
prediction. Thus the cross-validated PLS model is usually less subject to error of overspecification than the regression model.

## Predictive Ability of the Model

The predictive ability of the model is tested by a cross-validation method. A cross-validation procedure must be used to select the model having the highest predictive ability. The predictive ability of the obtained model is expressed in term of $r^{2} \mathrm{cv}$ or $\mathrm{q}^{2}$, which is define as:

$$
q^{2}=\frac{(S S Y-P R E S S)}{S S Y}
$$

where SSY is the sum of square of deviation between the affinities of the fitted set and their mean affinity:

$$
S S Y=\Sigma\left(Y_{\text {actual }}-Y_{\text {mean }}\right)^{2}
$$

and PRESS is the prediction error sum of squares obtained from the leave-one-out method:

$$
\text { PRESS }=\Sigma\left(Y_{\text {pred }}-Y_{\text {actual }}\right)^{2}
$$

where $Y_{\text {actual, }} Y_{\text {mean }}$ and $Y_{\text {pred }}$ are actual, mean and predicted values of the target property, respectively. The standard of error of prediction ( $S_{\text {PRESS }}$ ) is also considered and defined as:

$$
\begin{aligned}
& \text { ลถาบนวทยบรการ }
\end{aligned}
$$

where n is the number of compounds used in the study, k is the number of variables in the model.

The real predictive ability of each analysis is determined form a set of compounds not included in the training set. These molecules are aligned, and their activities are
predicted by each PLS analysis. The predictive $\mathrm{r}^{2}\left(\mathrm{r}^{2}\right.$ pred) value is based on molecules of the testing set only and is defined as:

$$
r_{p r e d}^{2}=\frac{(S D-P R E S S)}{S D}
$$

Where SD is the sum of the squared deviations between biological activities of the test set and mean activity of the training set molecules and PRESS is the sum of squared deviation between predicted and actual activity values for every molecule in the test set.

The optimum number of component is extracted from a previous cross-validated PLS analysis by examining the incremental change in $\mathrm{q}^{2}$ with each additional components corresponding to the minimum $\mathrm{S}_{\text {PRESS }}$ is used for next non-cross-validated PLS analysis. PLS analyses with non-cross-validation are then run with the optimum number of components of each alignment to derive the final QSAR model and corresponding conventional $\mathrm{r}^{2}$ and s .

### 5.1.4 Interpretation of CoMFA Results

Results of CoMFA are equations showing the contribution of energy fields at each lattice point. In order to facilitate the interpretation of the results, it is also displayed as coefficients (or standard deviation time coefficient or stdev*coeff) contour plot showing the regions in space where specific molecular properties increase or decrease the potency. The coloring is standardized as followings:

- The contours are colored in green and yellow for positive and negative steric effect, respectively. Positive steric contours show the regions where substituents increase the biological potency if occupied and the negative steric contours show the area where substituents decrease the potency.
- The contours are colored in blue and red for positive and negative electrostatic effect, respectively. The positive electrostatic contours indicate the region where positive charges increase the potency, whereas the negative electrostatic contours display the region where negative charge increase the potency.

The CoMFA process is summarized in Figure 5.2.

Figure 5.2 Flow chart of CoMFA methodology in this study.

### 5.2 Computational Methods

### 5.2.1 Conformation and Alignment Rule

The bioactive conformation of drug molecule, the conformation when it is bound to its target receptor, is usually used in the CoMFA study. However, this conformation is not known in our compounds. Therefore, two types of conformation were considered instead: 1) the conformation obtained from HF/3-21G optimization and 2) the conformation corresponding to the best docking configuration to heme (see chapter 6). For the first conformation type, the structures of all 32 compounds were optimized at HF/3-21G level and their atomic charges were subsequently assigned at the HF/6-31G(d) level using the Mulliken Population Analysis (MPA) method. The second conformation type was obtained by performing flexible docking calculations between each compound and heme (see details in Chapter 6). Fifteen alignment rules were used to study the influence of different alignments. For all alignments, the structures were adjusted using the "Fit Atom" option in the SYBYL ${ }^{70}$ which minimizes the root-mean-square (RMS) differences of selected atoms to the ones of the reference molecule. The most active compound 31 was used as the template for the alignment (see Figure 5.3).

Figure 5.3. Superimposition of all tricyclic 1,2,4-trioxane compounds using the alignment 13 and compound 31 as template (hydrogen atoms were omitted for clarity).

The selected atoms for the definition of alignment rules are shown in Table 5.1 and Figure 5.4.

Table 5.1 Atoms selected for the definition of alignment rules.

### 5.2.2 CoMFA Calculations

A regular three-dimensional lattice with $2 \AA$ spacing was created extending beyond molecular dimension of the largest molecule by $4.0 \AA$ in all directions. Twelve types of probe atoms were used, $+1.0 \mathrm{sp}^{3}$ carbon, $+1.0 \mathrm{sp}^{2}$ carbon, +1.0 sp carbon, +1.0 ar carbon, $-1.0 \mathrm{sp}^{3}$ oxygen, $-1.0 \mathrm{sp}^{2}$ oxygen, $+1.0 \mathrm{sp}^{3}$ nitrogen, $+1.0 \mathrm{sp}^{2}$ nitrogen, +1.0 sp nitrogen, +1.0 ar nitrogen, +1.0 am nitrogen, and +1.0 hydrogen. The steric (LennardJones 12,6 function) and electrostatic (Coulombic) interactions were calculated using the Tripos force field with a distance-dependent dielectric constant. The cut-off was set to 30 $\mathrm{kcal} / \mathrm{mol}$ for both fields. The AutoCoMFA column, which uses all the default setting values, was additionally calculated.

### 5.2.3 Partial Least Squares Regression Analysis

All models were investigated using the full cross-validated partial least squares method (leave-one-out) with CoMFA standard options for scaling of variables. Minimum-sigma (column filtering) was set to $2.0 \mathrm{kcal} / \mathrm{mol}$ to improve a signal-to-noise ratio by omitting those lattice points whose energy variation is below this threshold. To avoid an excessive number of components, the optimal number of components (onc) was selected as the one which results in an increase of the $q^{2}$ of more than $5 \%$ compared to
the model with fewer components. Subsequently, it was used for the PLS without crossvalidation to derive the $r^{2}$ statistics.

### 5.3 CoMFA Results and Discussions

### 5.3.1 Effect of Conformation and Alignment Rule

The CoMFA results of different conformations and the alignment rules for tricyclic 1,2,4-trioxanes are given in Table 5.2. From these results, it is clear that the conformation from HF/3-21G optimization give better predictive models than the those from the docking calculations for all alignments. The structural orientation of all 32 compounds obtained from docking calculations are quite different from each other while the optimized structures have almost the same conformation. The poor superimpose to the template due to variation of orientations in definitely effect to the derived model and yield a bad statistical results. Therefore, we considered the effect of alignment rules only on the conformation from HF/3-21G optimization. All models have $\mathrm{r}^{2}$ acceptable values, therefore only $\mathrm{q}^{2}$ are discussed. Alignments 1 and $2\left(\mathrm{q}^{2}=0.333\right)$ give the same results. The alignment number 3 give better $q^{2}$ statistics (0.385) than alignments 1 and 2 . Alignments 4, 5, 6 give lower $q^{2}$ values than alignment 3 . Considering alignments $7-11$, the better $q^{2}$ values of alignments 8,10 compared to $7,9,11$ indicate that rings $B$ and $C$ of tricyclic 1,2,4-trioxanes have more contribution to activity than ring A. For alignments 12-15, it was found that alignment 13 give higher $q^{2}$ value than other alignments. In addition, alignment 13 give the highest value among all 15 alignments used in this study. Therefore, alignment 13 was selected for further investigations.

| 15 | 0.356 | 5 | 0.940 | 0.212 | 5 | 0.947 |

### 5.3.2 Effect of Type of Probe Atom

Both steric and electrostatic fields are determined from the interaction energies between molecules and the selected probe atom. The type and charge of probe atom are significant to CoMFA results. Twelve types of probe atoms were selected, $+1.0 \mathrm{sp}^{3}$ carbon, $+1.0 \mathrm{sp}^{2}$ carbon, +1.0 sp carbon, +1.0 ar (aromatic) carbon, $-1.0 \mathrm{sp}^{3}$ oxygen, $-1.0 \mathrm{sp}^{2}$ oxygen, $+1.0 \mathrm{sp}^{3}$ nitrogen, $+1.0 \mathrm{sp}^{2}$ nitrogen, +1.0 sp nitrogen, +1.0 ar (aromatic) nitrogen, +1.0 am (amine) nitrogen and +1.0 hydrogen. Comparing among these twelve probe atom types, there is no significant difference (see Table 5.3). Therefore, the default setting for type and charge of probe atom, $\mathrm{C}-\mathrm{sp}^{3}$ with +1.0 charge were selected for further studies.

Table 5.3 Effect of Type of Probe Atom.

| Type | Charge | $\mathrm{q}^{2}$ | onc | $\mathrm{r}^{2}$ |
| :--- | :---: | :---: | :---: | :---: |
| C-sp $^{3}$ | +1.0 | 0.401 | 5 | 0.931 |
| C-sp $^{2}$ | +1.0 | 0.401 | 5 | 0.931 |
| C-sp | +1.0 | 0.401 | 5 | 0.931 |

| O-sp $^{3}$ | -1.0 | 0.398 | 5 | 0.939 |
| O-sp $^{2}$ | -1.0 | 0.398 | 5 | 0.939 |
| N-sp $^{3}$ | +1.0 | 0.407 | 5 | 0.939 |
| N-sp $^{2}$ | +1.0 | 0.407 | 5 | 0.939 |
| N-sp | +1.0 | 0.407 | 5 | 0.939 |
| N-ar | +1.0 | 0.407 | 5 | 0.939 |
| N-am | +1.0 | 0.407 | 5 | 0.939 |
| H | +1.0 | 0.403 | 5 | 0.937 |

### 5.3.3 Effect of Steric and Electrostatic Cut-offs

The steric and electrostatic cut-offs are used to filter unimportant data before the statistical analysis step. Therefore, their effect on the CoMFA results was investigated by varying their values to 10 and $30 \mathrm{kcal} / \mathrm{mol}$. The results are shown in Table 5.4., By setting the electrostatic cutoff to $30 \mathrm{kcal} / \mathrm{mol}$ and varying the steric cutoff to 10 and 30 $\mathrm{kcal} / \mathrm{mol}$, the resulting $\mathrm{q}^{2}$ values are equal ( 0.401 ) but the $\mathrm{r}^{2}$ values are slightly different ( 0.923 vs. 0.931 ). Therefore, the steric cut-off does not have significant effect. On the other hand, changing the electrostatic cut-off from 30 to $10 \mathrm{kcal} / \mathrm{mol}$ while keeping the steric cut-off constant at $30 \mathrm{kcal} / \mathrm{mol}$; both $\mathrm{q}^{2}$ and $\mathrm{r}^{2}$ values were decreased. Therefore, steric and electrostatic cut-off values $30 \mathrm{kcal} / \mathrm{mol}$ were selected for further studies.

Table 5.4 CoMFA results with different steric and electrostatic cut-offs.

| Steric Cut-off <br> $(\mathrm{kcal} / \mathrm{mol})$ | Electrostatic Cut-off <br> $(\mathrm{kcal} / \mathrm{mol})$ | $\mathrm{q}^{2}$ | onc | $\mathrm{r}^{2}$ |
| :---: | :---: | :---: | :---: | :---: |
| 30 | 30 | 0.401 | 5 | 0.931 |
| 10 | 30 | 0.401 | 5 | 0.923 |
| 30 | 10 | 0.375 | 5 | 0.927 |
| 10 | 10 | 0.385 | 5 | 0.913 |

### 5.3.4 CoMFA results

In order to access the real predictive ability of the model, all 32 compounds were divided into 2 sets, i.e., training set and testing set. Compounds 15, 20, 23 and 28 were randomly selected for the testing set. The remaining 28 compounds were used as the training set. The CoMFA results of the training set are illustrated in Table 5.5.

Table 5.5 CoMFA results of all 28 compounds.

| Model | $\mathrm{q}^{2}$ | onc | SPress $^{2}$ | $\mathrm{r}^{2}$ | S | F | Contribution Fraction |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  | Steric | Elec. |
| 1 | 0.490 | 6 | 0.342 | 0.972 | 0.080 | 121.506 | 0.591 | 0.409 |

From Table 5.5, although the CoMFA model has good statistical result (high $\mathrm{r}^{2}$ value) but its predictive power $\left(\mathrm{q}^{2}=0.490\right)$ is lower than the acceptable value $\left(\mathrm{q}^{2}=\right.$ 0.500 ). Since the $q^{2}$ value is sensitive to a compound with high residual value, an improvement of the $q^{2}$ value could be attained by omitting such compounds, as usually done in all CoMFA studies. Therefore, compounds with high residual, compounds 6,18 and 26 were omitted (see Table 5.6). Subsequently, the new model was evaluated and the results are given in Table 5.7. The predictive power $\left(\mathrm{q}^{2}\right)$ was improved to 0.524 with the onc of 4. A contribution ratio between steric and electrostatic fields of 3:2 indicate the importance of steric field.

Table 5.6 Predicted activities and residuals of 28 compounds in the training set.

## Analysis of CoMFA contour maps

The CoMFA contour maps of the model with the best "predictive" $\mathrm{r}^{2}\left(\mathrm{q}^{2}\right)$, model 2, are discussed below. Contour maps were generated as scalar products of coefficients and standard deviation (stdev*coeff). The CoMFA steric interactions are represented by green and yellow colored contours while electrostatic interactions are represented by red and blue colored contours. Bulky substituents are favored in green regions and disfavored in yellow regions. $\overline{\mathrm{n}}$ increase in positive charge is favored in blue regions while an increase in negative charge is favored in red regions

The steric contour plots of our model are illustrated in Figures 5.8-5.11. A large yellow contoupwas located around substituent group at the $\mathrm{C}_{3}$ position $\left(\mathrm{R}_{1}\right)$. It indicates that the steric at this position would diminish the activities. The alkyl substituent groups in compounds 2 and 3 are buried in this yellow region (see Figure 5.8A) and hence they have low activities. On the other hand, compounds 13-14 have only one carbon atom of phenyl substituent groups fall in this region (see Figure 5.8B). Thus, compounds 13-14 have higher activities than compounds 2 and 3.

Figure 5.8 CoMFA S.D.*coeff. Steric contour maps, (A) compounds 3 and (B) compounds 14 which have substituents at $C_{3}$ position $\left(R_{1}\right)$ are represented.

In Figure 5.9, there is no steric contour located on the substituent group at the $\mathrm{C}_{4}$ position ( $\mathrm{R}_{2}$ ) of compounds 22-24. This is possibly because only two compounds having $\mathrm{R}_{2}$ substituent were included in the training set of 25 compounds so their steric contribution to the model in the contour map is very small. Therefore, the CoMFA model does not represent their steric effect well.

Figure 5.9 CoMFA S.D.*coeff. Steric contour maps, compound 24 which has substituent at $C_{4}$ position $\left(R_{2}\right)$ is represented.

Green contour around $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ group at the $\mathrm{C}_{8 \mathrm{a}}$ position $\left(\mathrm{R}_{3}\right)$ indicate the steric favor of substituent at this position (see Figure 5.10). This contour map suggest that the tricyclic 1,2,4-trioxanes compounds with $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ substituents at the $\mathrm{C}_{8 \mathrm{a}}$ position would have high activities, e.g. compounds $25-32$. In addition, a small green contour was found around substituent group at the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$, which means that the methyl substitution at this position produced better activity than the hydrogen atom. For example, compounds with the methyl substitutent at the $\mathrm{C}_{4}$ position ( $\mathrm{R}_{2}$ ), compounds 30-32, showed higher activity than their unsubstituted compounds 25-27.

Figure 5.10 CoMFA S.D.*coeff, Steric contour maps, compound 31 which has substituent at $C_{8 a}$ position $\left(R_{3}\right)$ is represented. $G \widetilde{\sim} \cap 𠃌$

The green contour in the vicinity of $R_{4}$ is absent for compounds 16-21 (see Figure 5.11) although experimentally the steric occupancy with these bulky substituents increase the activities. Our CoMFA model would not describe well for compounds with sulfur atom in the substituent group.

Figure 5.11 CoMFA S.D.*coeff. Steric contour maps, compound 21 which has substituent at $\mathrm{C}_{12}$ position $\left(\mathrm{R}_{4}\right)$ is represented.

The electrostatic contour plots of our model are illustrated in Figures 5.12-5.15. A red contour is found around the carbon atom next to $C_{3}$ position $\left(R_{1}\right)$ (see Figure 5.12), therefore, compound with negative charge at this position will have high activity. For example, compounds 2-4 have atomic charge on carbon atom next to $\mathrm{C}_{3}$ position $\left(\mathrm{R}_{1}\right)$ of $-0.338,-0.344$ and -0.384 , respectively so compound 4 (activity 6.998 ) more active than compound 3 (activity 6.959) and compound 2 (activity 6.796) accordingly.

## สถาบันวิทยบริการ

จุฬาลงกรณ์มหาวิทยาลัย

Figure 5.12 CoMFA S.D.*coeff. Electrostatic contour maps, compound 14 which have substituent at $C_{3}$ position $\left(R_{1}\right)$ is represented.

A large blue contour is located around the first carbon atom of substituent group connected to the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$ indicating that highly positive charge at this position is required to enhance binding affinity. As example, compounds 22-24 (see Figure 5.13), the first carbon atoms of substituent group at the $\mathrm{C}_{4}$ position have atomic charges of $-0.346,0.000,0.023$, respectively, thus compound 24 display highly inhibition.

## สถาบันวิทยบริการ

จุฬาลงกรณ์มหาวิทยาลัย

Figure 5.13 CoMFA S.D.*coeff. Electrostatic contour maps, compound 24 which has substituent at $C_{4}$ position $\left(R_{2}\right)$ is represented.

A red contour is placed on carbon atom next to the $\mathrm{C}_{8 \mathrm{a}}$ position $\left(\mathrm{R}_{3}\right)$ (see Figure 5.14). The calculated atomic charge on carbon atom next to the $\mathrm{C}_{8 \mathrm{a}}$ position of compound 28 is -0.351 and of compound 31 is -0.366 . The charge of compound 31 is more negative than that of compound 28 hence compound 31 shows higher activity than compound 28.

Figure 5.14 CoMFA S.D.*coeff. Electrostatic contour maps, compound 31 which has substituent at $\mathrm{C}_{8 \mathrm{a}}$ position $\left(\mathrm{R}_{3}\right)$ is represented.

Considering compounds 16 -21 with substituent group at the $\mathrm{C}_{12}$ position $\left(\mathrm{R}_{4}\right)$, no electrostatic contour was observed around the $\mathrm{C}_{12}$ position (see Figure 5.15). This means that the electrostatic field contributed from substituent group of such compounds has no relationship with biological activity. It is also interesting to note that compounds 19-21 containing sulfone $\left(\mathrm{SO}_{2}\right)$ in the substituent groups $\left(\mathrm{R}_{4}\right)$ attached to the $\mathrm{C}_{12}$ position display significantly malarial inhibition, about 2-6 times compared to compounds 16-18 containing sulfide (S) in the substituent groups ( $\mathrm{R}_{4}$ ). Our quantum chemical calculations show that the atomic charge of S in $\mathrm{SO}_{2}-\mathrm{R}_{4}$ substituent groups of compounds 19-21 are 15 times greater than that in $S-\mathrm{R}_{4}$ substituent groups of compounds $16-18$. This remark is interesting for further work.

Figure 5.15 CoMFA S.D.*coeff. Electrostatic contour maps, compound 21 which has

## 

The effects of some adjustable parameters on CoMFA results of tricyclic 1,2,4trioxane derivatives were studied. The conformation obtained from the HF/3-21G optimizations gave better results than those from the docking calculations. Fifteen alignment rules were used to study the influence of different alignments, the alignment 13 yield the best $\mathrm{q}^{2}$ value, thus, alignment 13 was selected for CoMFA study. From the investigations, the type of probe atom does not have significant effect on the $q^{2}$ value.

Therefore, the default setting for probe atom type, C-sp ${ }^{3}$ with +1.0 charge was chosen. And the default setting for steric and electrostatic cut-off values $30 \mathrm{kcal} / \mathrm{mol}$ was shown to be the suitable values. These setting were subsequently used for the training set (28 compounds) to derive the CoMFA model. The predictive power ( $\mathrm{q}^{2}=0.490$ ) of the obtained model is lower than the acceptable value. Therefore 3 compounds with high residual values, i.e. compounds 6,18 and 26 were excluded and the predictive power was significantly improved $\left(q^{2}=0.524\right)$. The analysis of CoMFA contour maps in this study provides insight into the possible modification of the molecules for better activity.

## CHAPTER 6

## MOLECULAR DOCKING

### 6.1 Introduction

Computer aided rational drug design, which enable a large reduction of both budget and time, is explosively growth in the area of drug design and discovery over the past few years. One of the most popular methods for investigation of interactions between drug and receptor is a molecular docking method. It provides an estimate of a binding mode between drug and receptor. With an increasing number of known receptor structures available, interest in molecular docking is rapidly increased and much progresses have been made in recent years. An important feature of any docking method is an energy function that is capable of predicting binding modes.

A mechanism of action of any drug is very important in drug development. Generally, drug compound binds with a specific target, a receptor, to mediate its effects. Therefore, suitable drug-receptor interactions are required for high activity. To understand the nature of these interactions, theoretical calculations, in particular the molecular docking method, seem to be a proper tool for gaining such understanding. The obtained docking results will give information on how to modify chemical structure of the drug to achieve suitable interactions. Hence, this could bring about a development of new and more effective drugs.

Simplified tricyclic 1,2,4-trioxane analogues has similar structure to artemisinin. They contain peroxide linkage, rings $\mathrm{A}, \mathrm{B}$ and C but lack of tactone ring D . Therefore, they are proposed to have similar mechanism as artemisinin ${ }^{71,72}$ as shown in Figure 6.1, It has been accepted that free iron from heme generated within the malarial parasite is responsible for activating the tricyclic 1,2,4-trioxane antimalarials to form cytotoxic radical intermediates. The Fe atom can make a reductive cleavage of the $\mathrm{O}-\mathrm{O}$ bond by coordinating to either $\mathrm{O}_{1}$ or $\mathrm{O}_{2}$. In Pathway A, heme iron attacks tricyclic 1,2,4-trioxane
 form $\mathrm{C}_{4}$ free radical (2A). The compound 2 A is changed to epoxide (3A) and then ultimately to hydroxylated product (4A). On the other hand, in Pathway B, heme iron
attacks tricyclic 1,2,4-trioxane at $\mathrm{O}_{1}$ position and produces free radical at $\mathrm{O}_{2}$ position (1B). Then, the $\mathrm{C}_{3}-\mathrm{C}_{4}$ bond is cleaved to give a carbon radical at $\mathrm{C}_{4}(2 \mathrm{~B})$ after that ring closure is occurred to form ring-contracted product (3B). ${ }^{73,74,75}$

Figure 6.1 Proposed mechanisms for the $\mathrm{Fe}(\mathrm{II})$-induced activation of simplified 1,2,4trioxanes.

In this thesis works, the molecular docking framework was applied to investigate and predict antimalarial activities of tricyclic 1,2,4-trioxane derivatives. The relationships between biological activity and properties obtained from dock results such as binding energy, $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $\mathrm{O}_{2}-\mathrm{Fe}$ distance, and $\mathrm{O}_{13}-\mathrm{Fe}$ distance were studies. It is also expected that results might be able to give some information about the mode of action.

### 6.2 Docking Theory

The Binding Energy in AutoDock2.4 program can be calculated by van der waals potential and electrostatic potential terms.

## Van der Waals Potential Energy

The pairwise potential energy, $\mathrm{V}(\mathrm{r})$, between two non-bonded atoms can be expressed as a function of internuclear separation, $r$, as follows,

$$
\begin{equation*}
V(r)=\frac{A e^{-b r}}{r}-\frac{C_{6}}{r^{6}} \tag{6.1}
\end{equation*}
$$

Graphically, if $\mathrm{r}_{\text {eqm }}$ is the equilibrium internuclear separation and $\varepsilon$ is the well depth at $\mathrm{r}_{\text {eqm }}$, then:

Figure 6.2 Graph showed relationship between internuclear distance (r) and well-depth ( $\varepsilon)$

The exponential, repulsive, exchange energy is often approximated thus,

$$
\begin{equation*}
\frac{A e^{-b r}}{r} \approx \frac{C_{12}}{r^{12}} \tag{6.2}
\end{equation*}
$$

Hence pairwise-atomic interaction energies can be approximated using the following general equation,

$$
\begin{equation*}
\mathrm{V}(\mathrm{r}) \approx \frac{\mathrm{C}_{\mathrm{n}}}{\mathrm{r}^{\mathrm{n}}}-\frac{\mathrm{C}_{\mathrm{m}}}{\mathrm{r}^{\mathrm{m}}}=\mathrm{C}_{\mathrm{n}} \mathrm{r}^{-\mathrm{n}}-\mathrm{C}_{\mathrm{m}} \mathrm{r}^{-\mathrm{m}} \tag{6.3}
\end{equation*}
$$

where m and n are integers.

We can derive a general relationship between the coefficients, equilibrium separation and well depth as follows. At the equilibrium separation, $\mathrm{r}_{\text {eqm }}$, the potential energy is a minimum and equal to the well depth: in other words, $\mathrm{V}\left(\mathrm{r}_{\mathrm{eqm}}\right)=-\varepsilon$. The derivative of the potential with respect to separation will be zero at the minimum potential:

$$
\frac{\mathrm{dV}}{\mathrm{dr}}=-\frac{\mathrm{nC}_{\mathrm{n}}}{\mathrm{r}^{\mathrm{n}+1}}+\frac{\mathrm{mC}_{\mathrm{m}}}{\mathrm{r}^{\mathrm{m}+1}}=0
$$

so:
therefore:

$$
\frac{\mathrm{nC}_{n}}{\mathrm{r}^{\mathrm{n}+1}}=\frac{\mathrm{mC}_{m}}{\mathrm{r}^{\mathrm{m}+1}}
$$

Substituting $\mathrm{C}_{\mathrm{m}}$ into the original equation for $\mathrm{V}(\mathrm{r})$, then at equilibrium we obtain,

$$
\begin{align*}
& \mathrm{C}_{\mathrm{n}}\left(\frac{\mathrm{mr}_{\text {eqm }}^{\mathrm{m}}-\mathrm{nr}_{\text {eqm }}^{\mathrm{n}} \mathrm{r}_{\text {eqm }}^{(\mathrm{m}-\mathrm{n})}}{\mathrm{mr}_{\mathrm{eqm}}^{\mathrm{n}} \mathrm{r}_{\mathrm{cqm}}^{\mathrm{m}}}\right)=-\varepsilon \tag{6.5}
\end{align*}
$$

Rearranging, equation (6.5), substituting $C_{m}$ into the original equation for $V(r)$, then at equilibrium we obtain:

$$
\begin{equation*}
C_{n}=\frac{m}{n-m} \varepsilon r_{e q m}^{n} \tag{6.6}
\end{equation*}
$$

Therefore, the coefficient $\mathrm{C}_{\mathrm{n}}$ can be expressed in terms of $\mathrm{n}, \mathrm{m}, \varepsilon$ and $\mathrm{r}_{\mathrm{eqm}}$, then substituent $C_{n}$ into equation (6.4) for $C_{m}$

$$
\begin{equation*}
C_{m}=\frac{n}{n-m} \varepsilon_{e q m}^{m} \tag{6.7}
\end{equation*}
$$

then we obtain the general equation for $\mathrm{V}(\mathrm{r})$ at any $\mathrm{n}, \mathrm{m}$ :

$$
\begin{equation*}
\mathrm{V}(\mathrm{r}) \approx \frac{\frac{\mathrm{m}}{\mathrm{n}-\mathrm{m}^{\varepsilon \mathrm{eqm}}} \mathrm{r}_{\mathrm{n}}^{\mathrm{n}}}{\mathrm{r}^{\mathrm{n}}}-\frac{\frac{\mathrm{n}}{\mathrm{n}-\mathrm{m}^{2}} \varepsilon \mathrm{r}_{\mathrm{eqm}}^{\mathrm{m}}}{\mathrm{r}^{\mathrm{m}}} \tag{6.8}
\end{equation*}
$$

$\mathrm{C}_{\mathrm{n}}$ and $\mathrm{C}_{\mathrm{m}}$ are constants whose values depend on the depth of the energy well and the equilibrium separation of the two atoms nuclei. They can be calculated equation (6.9) and (6.10) by:

$\mathrm{r}_{\text {eqm }}$ are Van der Waals radius of a given atom for all pairwise distances.

and the Lennard-Jones 12-6 potential becomes:

$$
\begin{equation*}
V_{12-6}(r)=4 \varepsilon_{X Y}\left[\left(\frac{\sigma}{r}\right)^{12}-\left(\frac{\sigma}{r}\right)^{6}\right] \tag{6.11}
\end{equation*}
$$

.Hence, the coefficients $\mathrm{C}_{12}$ and $\mathrm{C}_{6}$ are given by:

$$
\begin{aligned}
& C_{12}=\varepsilon_{X Y} r_{e q m, X Y}^{12} \\
& C_{6}=2 \varepsilon_{X Y} r_{e q m, X Y}^{6}
\end{aligned}
$$

Typically the 12-6 Lennard-Jones parameters $(\mathrm{n}=12, \mathrm{~m}=6$ ) are used to model the Van der Waals' forces experienced between two instantaneous dipoles.

## Electrostatic Potential Grid Maps

In addition to the atomic affinity grid maps, AutoDock requires an electrostatic potential grid map. Partial atomic charges must be assigned to the macromolecule receptor. AutoGrid calculates Coulombic interactions between the macromolecule and a probe of charge e,$+1.60219 \times 10^{-19} \mathrm{C}$; there is no distance cutoff used for electrostatic interactions. A sigmoidal distance-dependent dielectric function is used to model solvent screening, based on the work of Mehler and Solmajer. ${ }^{76}$

$$
\varepsilon(r)=\frac{A+B}{1+k e^{-\lambda B r}}
$$

where parameters are:

$$
\begin{aligned}
\mathrm{B} & =\varepsilon_{0}-\mathrm{A} \\
\varepsilon_{0} & =\text { the dielectric constant of bulk water at } 25^{\circ} \mathrm{C}=78.4 \\
\mathrm{~A} & =-8.5525 \\
\lambda & =0.003627 \\
\mathrm{k} & =7.7839 \\
\mathrm{r} & =\text { distance }
\end{aligned}
$$

AutoDock is a program for docking small flexible ligands to a rigid protein or rigid macromolecule. It combines a fast energy evaluation through precalculated grids of affinity potentials with a Monte Carlo-simulated annealing search algorithm. It was developed by the A. J. Olson's group. ${ }^{77}$ AutoDock uses an atomic representation of the ligand. Flexible torsions in the ligand may be defined with the utility AutoTors. The
macromolecule is treated as rigid and represented by a set of affinity grids. The grids are generated with AutoGrid on the basis of typical force field terms for van der Waals and Coulombic interactions. At every grid points, the interaction energy between a probe atom/probe charge and the whole macromolecule is calculated, supplying a "map" of affinity potentials for each defined atom type, as well as a map for the electrostatic potential. These maps serve as look-up tables for the calculation of the interaction energy during the docking process. The actual docking is performed with the main AutoDock program. To search for suitable sites of interaction, the ligand is moved through the receptor near space by small random displacements along translational, rotational, and torsional degrees of freedom. Evaluation of the interaction energy at every steps is followed by application of the Metropolis algorithm to decide on the acceptance of the new position and thus on the point from which the search will proceed. Since this is coupled to a process of simulated annealing, a wide region of conformational space can be searched, while immediately finishing in local minima next to the starting position is avoided.

The individual components of the AutoDock program, whose basics will be explained below, are: AutoTors, AutoGrid, and AutoDock.

AutoTors is the simplest of the components-it defines which bonds in the ligand are rotatable, affecting the degrees of freedom (DF) of the ligand, and thus the complexity of the computations. ${ }^{77}$ Each rotatable torsional angle adds an extra DF, so large ligands with many torsional angles quickly become too complex to compute.

AutoGrid pre-calculates a three-dimentinal grid of interaction energies based on the macromolecular target using the AMBER force fields. Since the structure of the receptor is rigid and known, interaction energies between the probe and surrounding atoms can be calculated at each point in the grid and-stored in a table. Additional tables are made for each atom type in the ligand, taking into account dispersion/repulsion and hydrogen bonding energies. A second grid is made to allow for electrostatic effects, using a probe with a single positive charge. After the grid has been completed, AutoDock can begin the simulation. First, the ligand moves randomly in any one of six degrees of freedom (either translation or rotation) and the energy of the new ligand "state" is calculated. If the energy of the new state is higher than the old state, the new one is
automatically accepted as the next step in docking. However, if it is higher, then the step is accepted by the following probability function:

$$
P(\Delta E)=e^{\frac{-\Delta E}{k_{B} T}}
$$

where $\mathrm{k}_{\mathrm{B}}=$ Boltzmann's constant $\left(1.38 \times 10^{-23} \mathrm{~J} / \mathrm{K}\right), \Delta \mathrm{E}=$ energy, $\mathrm{T}=$ temperature $(\mathrm{K})$

The system starts at a high temperature T in order to accept most initial steps. The steps are cycled, and at the beginning of each new cycle, the temperature is reduced, making it more it progressively more difficult for the docking to precede to a new step. A final low energy bound conformation is returned.

### 6.3 Computational Methods

The docking calculations were performed using the automated docking program, AutoDock 2.4 software ${ }^{78,79}$ The AutoDock employs a simulated annealing Monte Carlo simulation in combination with a rapid grid-based energy evaluation method. ${ }^{80}$ The rapid energy evaluation is achieved by precalculating atomic affinity potentials for each atom type present in the ligand molecule. For example, tricyclic 1,2,4-trioxane has only three atom types in the molecule (carbon, oxygen, and hydrogen); therefore, three atomic affinity potentials, i.e., receptor-carbon, receptor-oxygen, and receptor-hydrogen interaction energies, are required. To create these potentials, a grid map, which is a regular three-dimensional lattice with a selected grid spacing, is placed covering the active site of the receptor (Figure 6.3).

Considering the C atomic affinity potential, a probe atom, which is the same atom type used to create the atomic affinity potential (in this case is carbon), is placed at the edge of every lattice points. For each lattice point, the interaction energy between the probe atom and receptor atoms within a non-bonded cutoff radius of $8 \AA$ is calculated using the Lennard-Jones 12-6 potential and is assigned to that lattice point. The O and H atomic affinity potentials are calculated in the same manner as that of the carbon.

In addition to the atomic affinity grid maps, an electrostatic potential grid map of the receptor molecule is created. The electrostatic interaction energy between the receptor and a probe of charge $\mathrm{e},+1.60219 \times 10^{-19} \mathrm{C}$ is calculated using a Coulomb potential. A
sigmoidal distance-dependent dielectric function based on the work of Mehler and Solmajer ${ }^{76}$ is used to a model solvent effect.

Figure 6.3 Grid base energy evaluation.

In one docking calculation, the simulations were performed for 100 annealing cycles. At the first cycle, the initial annealing temperature (RT) was set $1390.9 \mathrm{cal} / \mathrm{mol}$ and then the temperature was reduced at the rate of 0.90 per cycle. During each cycle, the ligand was gradually moved around the receptor molecule by a random displacement with a maximum translation step of $0.2 \AA$ and a maximum orientation step of 50 . The energy of new configuration was then calculated. The selection of the new configuration was based on the Metropolis algorithm. ${ }^{79}$ The cycle terminates if the ligand makes 30,000 rejected moves. Then the simulation moves to the next cycle.

Since the Monte Carlo simulation is based on random movements, the final docked configuration depends on the starting configuration. In order to avoid any bias and to generate as many final docked configurations as possible, the starting configuration was assigned in a random manner for each docking calculation and 100 docking calculations were performed. A cluster analysis was used to categorize all 100 docked configurations into groups. Configurations with root-mean-square-deviation (rmsd) values of less than $1 \AA$ were grouped together. In each group, the lowest energy configuration was selected as the representative of that group. The "\% Frequency" was used to represent the number of members (configurations) in each group. Our attention
was focused to the group with the highest \% Frequency or "the most frequency configuration". And this configuration is most probably corresponding to the docked configuration in the real system.

### 6.4 Determination of Suitable Docking Parameters

Because a core structure of trioxane compounds is similar to that of artemisinin compounds, dock parameters of artemisinins taken from our previous works ${ }^{80}$ were used as the initial setting as following. A grid map of dimension $25 \times 25 \times 25 \AA^{3}$ with a grid spacing of $0.50 \AA$ was employed. For the simulated annealing calculations, 100 docking runs with 100 annealing cycles per run were performed. A cycle terminated if the ligand makes either 30,000 accepted or 30,000 rejected moves. An initial annealing temperature, RT, was given as $100 \mathrm{kcalmol}^{-1}$ with a reduction factor of 0.90 . The combined AMBER/MMFF parameters for the Lennard-Jones 12,6 potentials and the Coulomb potentials were taken from authors of the program. ${ }^{81}$ The docking results obtained by this initial set of parameters seem to be not suitable for trioxane compounds. Therefore, investigations of important parameters grid dimension, grid spacing, starting temperature $\left(\mathrm{T}_{\mathrm{s}}\right)$, final temperature $\left(\mathrm{T}_{\mathrm{f}}\right)$, and temperature reduction rate factor were carried out to establish appropriate values. In order to reduce computing time for the investigations of parameters affecting docking results, only four compounds, namely 4,8 , 10 , and 15 , were used.

### 6.4.1 Grid Dimension

The AutoDock program uses the Monte Carlo simulation for searching docking conformation. As energy of a molecular system is calculated for every movements in the simulation, it is very time consuming process to evaluate the energy by a direct method. In order to avoid such situation, the AutoDock employs a rapid grid-based energy evaluation method. Therefore, it is necessary to investigate effects of the grid dimension and the grid spacing on docking results. Three different grid boxes with dimensions of $30 \times 30 \times 30 \AA^{3}, 25 \times 25 \times 25 \AA^{3}$ and $20 \times 20 \times 20 \AA^{3}$ were used. The starting temperature of $50,327.1 \mathrm{~K}$, the final temperature of 1.3 K , the temperature reduction rate of 0.90 , and
the grid spacing of $0.50 \AA$ were used for all calculations. The results are given in Table 6.1

Table 6.1 Docking results of heme and 4 derivatives of 1,2,4-trioxane compounds with three different grid dimensions.

| Compound <br> No. | Binding <br> Energy (kcal/mol) | \% <br> Frequency | $\mathrm{O}_{1}-\mathrm{Fe}$ <br> distance <br> (A) | $\mathrm{O}_{2}$-Fe <br> distance <br> ( $\AA$ ) | $\mathrm{O}_{13}-\mathrm{Fe}$ <br> distance <br> ( $\AA$ ) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| A. Grid dimension $30 \times 30 \times 30 \AA^{3}$ |  |  |  |  |  |
| 4 | -30.69 | 43 | 1.99 | 2.96 | 4.75 |
| 8 | -31.52 | 22 | 2.11 | 2.98 | 4.95 |
| 10 | -30.37 | 21 | 2.14 | 2.97 | 4.86 |
| 15 | -28.69 | 20 | 5.56 | 5.13 | 4.78 |
|  | -31.57 | 18 | 2.17 | 3.05 | 4.93 |
| B. Grid dimension $25 \times 25 \times 25 \AA^{3}$ |  |  |  |  |  |
| 4 | -30.65 | 39 | 1.96 | 2.96 | 4.78 |
| 8 | -31.53 | 30 | - 2.09 | 2.97 | 4.90 |
| 10 | -30.28 | 4-35 | 2.00 | 2.91 | 4.80 |
| 15 | -28.71 | 21 | 5.55 | 5.13 | 4.77 |
|  | -31.27 | 17 | 2.14 | 2.93 | 4.93 |
| C. Grid dimension $20 \times 20 \times 20 \AA^{3}$ |  |  |  |  |  |
| 4 | -30.84 | 55 | 1.98 | 2.94 | 4.81 |
| 8 | -31.91 e | 37 | 2.10 | 3.06 | 4.94 |
| 10 | -30.50 | $229 /$ | e192.01 | 2.96 | 4.83 |
| 15 | -32.01 | 29 | 2.09 | 2.92 | 4.87 |

The results from grid dimensions of $25 \times 25 \times 25 \AA^{3}$ and of $30 \times 30 \times 30 \AA^{3}$ are similar. In compounds 4,8 , and 10 the distance between heme iron and $\mathrm{O}_{1}$ is shorter than that of $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$ which indicates that heme iron interacts with $\mathrm{O}_{1}$ more preferably than $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$. On the other hand, compound 15 has the $\mathrm{O}_{13}-\mathrm{Fe}$ as the shortest distance. This distance is too large to account for any meaningful interactions. The compound 15 docks underneath the porphyrin plane instead of over the plane like in other compounds.

However, its second highest frequent configuration which has the lowest energy, has $\mathrm{O}_{1-}$ Fe distance as the shortest distance. Unlike the first two cases, results from the grid dimension of $20 \times 20 \times 20 \AA^{3}$ indicated that all 4 compounds have $\mathrm{O}_{1}-\mathrm{Fe}$ as the shortest distance. It can be seen that heme iron prefers to bind with the endoperoxide linkage of 1,2,4-trioxane compounds at the $\mathrm{O}_{1}$ position.

Comparing these three grid dimensions, the $20 \times 20 \times 20 \AA^{3}$ size give lower energy and larger number of member in the most frequency cluster group. In addition, the most occurring configuration in compound 15 has $\mathrm{O}_{1}$-Fe shortest distance which is in the same range as the other compounds. This is possibly due to its smaller grid dimension that does not allow 1,2,4-trioxane to move away from heme molecule. Therefore, the grid dimension of $20 \times 20 \times 20 \AA^{3}$ was chosen for further calculations.

### 6.4.2 Grid Spacing

The investigations on the effects of grid spacing were preformed by using grid spacing 0.40 and $0.50 \AA$. The results are shown in Table 6.2.

Table 6.2 Docking results of heme and 4 derivatives of 1,2,4-trioxane compounds with two different grid spacings.

| Compound No. | Binding <br> Energy <br> ( $\mathrm{kcal} / \mathrm{mol}$ ) | $\begin{gathered} \% \\ \text { Frequency } \\ \hline \end{gathered}$ | $\mathrm{O}_{1}-\mathrm{Fe}$ distance $(\AA)$ | $\mathrm{O}_{2}-\mathrm{Fe}$ distance ( $\AA$ ) | $\mathrm{O}_{13}-\mathrm{Fe}$ distance <br> (Å) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| A. grid spacing $0.50 \AA$ |  |  |  |  |  |
| 4 | -30.84 | 55 | $0^{1.98}$ | ${ }_{2} 2.94$ | 4.81 |
| 86 | 6-31.91 | 137 | C 2.10 | - 3.06 | 4.94 |
| 10 | -30.50 | $22 \sigma$ | 2.01 | 2.96 | 4.83 |
| 915/ | $6^{-32.01}$ | d 2900 | /2.09 ${ }^{\text {// }}$ | C 2.92 O | 4.87 |
| B. grid spacing $0.40 \AA$ |  |  |  |  |  |
| 4 | -31.71 | 40 | 1.98 | 2.94 | 4.81 |
| 8 | -32.63 | 33 | 2.02 | 2.82 | 4.80 |
| 10 | -31.32 | 24 | 1.94 | 2.84 | 4.75 |
| 15 | -32.89 | 37 | 1.99 | 2.91 | 4.80 |

The dock results using grid spacing of $0.40 \AA$ have shorter $\mathrm{O}_{1}-\mathrm{Fe}$ than those with grid spacing of $0.50 \AA$ except compound 4 , which are equal. Moreover, binding energies obtained with grid spacing of $0.40 \AA$ are lower than those with grid spacing of $0.50 \AA$. Thus, the grid spacing of $0.40 \AA$ was used for further calculations.

### 6.4.3 Starting Temperature $\left(T_{s}\right)$, Final Temperature $\left(T_{f}\right)$ and Temperature Reduction Rate

The AutoDock program employs a simulated annealing method to find a global energy minimum of drug-receptor complex. In this method, the annealing is defined as a process where the temperature of a molten substance is gradually reduced until the material crystallizes. Hence, the rate of decreasing temperature is very important. The temperature should be slowly lowering so that there is enough time for the substance to attain thermal equilibrium within each stage. The temperature should be kept reducing until a suitable value or the best solution is obtained. Therefore, the temperature reduction rate should be carefully controlled. In this study, the effects of the starting temperature, the final temperature, and the temperature reduction rate were investigated. The results are shown in Tables 6.3, 6.4 and 6.5, respectively.

| 15 | -32.72 | 52 | 1.96 | 2.87 | 4.77 |

The effects of starting temperature were investigated. Three starting temperatures $50,327.1 \mathrm{~K}, 2,516.4 \mathrm{~K}$ and 700 K were selected. The grid dimension of $20 \times 20 \times 20 \AA^{3}$ with the grid spacing of $0.40 \AA$ and the final temperature of 1.3 K and the temperature reduction rate of 0.90 were used. The results are shown in Table 6.3. The results from three different starting temperature are similar. The distance between heme iron and $\mathrm{O}_{1}$ is shorter than that of $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$, which indicates that heme iron interacts with $\mathrm{O}_{1}$ more preferably than $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$. It is found that starting temperature 700 K and $2,516.7 \mathrm{~K}$ give comparable results. Consider the lesser CPU time the temperature 700 K is therefore chosen for the calculation.

|  | -29.74 | 12 | 2.04 | 2.91 | 4.74 |
| C. $\mathrm{T}_{\mathrm{f}}=0.02 \mathrm{~K}$ |  |  |  |  |  |
| 4 | -32.79 | 42 | 1.94 | 2.82 | 4.72 |
| 8 | -34.35 | 49 | 1.96 | 2.76 | 4.74 |
| 10 | -32.97 | 54 | 2.00 | 2.89 | 4.81 |
| 15 | -34.34 | 49 | 1.96 | 2.77 | 4.77 |

The effects of final temperature were investigated. Three final temperatures 1.3 K , 129.7 K and 0.02 K were selected. The grid dimension of $20 \times 20 \times 20 \AA^{3}$ with the grid spacing of $0.40 \AA$ and the starting temperature of 700 K and the temperature reduction rate of 0.90 were used. The results are shown in Table 6.4. Considering the results with final temperature 1.3 K of compound $4,8,10$ and 15 the distance between heme iron and $\mathrm{O}_{1}$ is shorter than that of $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$, which indicates that heme iron interacts with $\mathrm{O}_{1}$ more than preferably than $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$. Considering the results obtained with final
temperature of 129.7 K , the docked configurations were clustered into too many groups which consist of only a few members. The results from final temperature 0.02 K are similar to those with final temperature 1.3 K but the energy is lower. Therefore, the final temperature 0.02 K was chosen for further calculations.

| 4 | -32.95 | $5^{54} 90$ | $\rho 19^{2.01}$ | ${ }^{2.89}$ | 4.81 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 86 | 6-34.39 | 150 | -1.97 | \| 2.76 | 4.74 |
| $2^{10} 9 / 9$ | $\begin{gathered} -24.09 \\ 6-29.67 \end{gathered}$ | $\approx 48{ }^{48}$ | $9 \% \stackrel{4.00}{1.850} 9$ | $e^{4.77} 2.66$ | $\begin{aligned} & 5.95 \\ & 4.62 \end{aligned}$ |
| 15 | -34.40 | 48 | 1.95 | 2.78 | 4.73 |

The effects of temperature reduction rate were investigated. Three temperature reduction rates $0.90,0.95$ and 0.99 were selected. The grid dimension of $20 \times 20 \times 20 \AA^{3}$ with the grid spacing of $0.40 \AA$ and the starting temperature of 700 K and the final
temperature of 0.02 K were used. The results are shown in Table 6.5. Considering results from temperature reduction rate 0.90 , the distance between heme iron and $\mathrm{O}_{1}$ is shorter than that of $\mathrm{O}_{2}$ and $\mathrm{O}_{13}$. The temperature reduction rate 0.95 indicated that all four compounds having shorter $\mathrm{O}_{1}-\mathrm{Fe}$ distance are the most probable docking configuration. However, compound 10 has very long $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $4.02 \AA$, which is too large to account for any intently interactions. Nevertheless, its second highest frequent configuration which has the lowest energy, has $\mathrm{O}_{1}-\mathrm{Fe}$ distance with in the same range as the others compounds. For temperature reduction rate 0.99 , the obtained results is similar to those of temperature reduction rate 0.95 . As the temperature reduction rate of 0.90 gives a better results and requires less calculation time, it seem to be an appropriate choice for further studies.

### 6.5 Docking of All 32 compounds

All suitable parameters determined from the previous section were employed for the docking calculations of all 32 compounds. These derivatives were optimized at $\mathrm{HF} / 3-21 \mathrm{G}$ and the atomic charges were calculated at the HF/6-31G(d) level. The atomic charges of heme were assigned at the $\mathrm{HF} / 6-311 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level. The docking results of 32 derivatives and heme are given Table 6.6. The distances from $\mathrm{Fe}^{2+}$ to $\mathrm{O}_{1}, \mathrm{O}_{2}$ and $\mathrm{O}_{13}$ are in the range of 1.84 to $2.27 \AA, 2.38$ to $3.11 \AA$, and 4.51 to $4.94 \AA$, respectively. The most occuring configurations in most tricyclic 1,2,4-trioxane compounds have $\mathrm{O}_{1}$ pointing toward the heme iron with the compound are over the porphyrin plane(see Figure 6.5) except compounds 16-21 which have $\mathrm{O}_{2}$ pointing toward the heme iron(see Figure 6.6). The replacement of the oxygen atom by sulfur atom at the $\mathrm{C}_{12}$ position in compounds 16 to 21 has significant effect on the docking results. This structure facilitates the encroachment of $\mathrm{Fe}^{2+}$ to $\mathrm{O}_{2}$ more than $\mathrm{O}_{1}$ due to steric effect is more pronounce than electrostatic effect. Consider the electrostatic effect, the partial charges of $\mathrm{O}_{1}$ and $\mathrm{O}_{2}$ are not different, therefore the preference for heme iron to bind with $\mathrm{O}_{1}$ and $\mathrm{O}_{2}$ is equal. For steric effect, the bulky substituent $R_{4}$ is closer to $O_{1}$ than $O_{2}$ will hinder heme to approach $\mathrm{O}_{1}$ and thus interacts with $\mathrm{O}_{2}$. The substituent groups at $\mathrm{C}_{3}$ position $\left(\mathrm{R}_{1}\right)$ of compounds 1-15 cause the steric hindrance at these positions, despite partial charges of $\mathrm{O}_{2}$ are more negative than $\mathrm{O}_{1}$, heme iron did not dock at the $\mathrm{O}_{2}$, heme iron prefers to approach at the
$\mathrm{O}_{1}$ position. It is revealed that the steric effect at $\mathrm{C}_{3}$ position $\left(\mathrm{R}_{1}\right)$ in compounds $1-15$ is dominant than electrostatic contribution. Compounds 22-24 with substituent groups at the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$, the most frequency configurations in those compounds have $\mathrm{O}_{1}$ pointing toward the heme iron. The reason may be due to its structure. The substituent groups at the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$ hinder the heme iron to approach at the $\mathrm{O}_{2}$ side but facilitate the approach of heme iron to the $\mathrm{O}_{1}$ side. Moreover, the partial charges of compounds 22-24 at the $\mathrm{O}_{1}$ position are more negative than $\mathrm{O}_{2}$ position. Therefore, both steric and electrostatic effect are promoted for docking of these compounds. Compounds 25-32 have substituent groups at the $\mathrm{C}_{4}$ and/or $\mathrm{C}_{8 \mathrm{a}}$ positions ( $\mathrm{R}_{2}$ and/or $\mathrm{R}_{3}$ ), the highest frequency configurations in those compounds have $\mathrm{O}_{1}$ pointing toward the heme iron. This suggested that electrostatic effect contributions to activity more than steric effect because the substituent groups at the $\mathrm{C}_{8 \mathrm{a}}$ position $\left(\mathrm{R}_{3}\right)$ is far from the endoperoxide linkage, steric effect should not play dominate role on the binding characteristic to heme. The partial charges of compounds $25-32$ at the $\mathrm{O}_{1}$ position are more negative charge than $\mathrm{O}_{2}$ position, these support the hypothesis of only electrostatic effect is the main features for activity. The superimposed docking configurations between heme and 32 derivative of 1,2,4-trioxane compounds are illustrated in Figure 6.3.

The Correlations between antimalarial activities and properties from docking calculations, i.e., binding energy, $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $\mathrm{O}_{2}$-Fe distance and $\mathrm{O}_{13}-\mathrm{Fe}$ distance of 32 derivatives of $1,2,4$-trioxane compounds were investigated. No significant relationship was found as indicated by $\mathrm{r}^{2}$ values of $0.009,0.010,0.003$ and 0.011 , respectively.

### 6.6 Docking Summary

The molecular docking method using the simulated annealing Monte Carlo simulations was employed to investigate the binding between heme and 32 derivatives of tricyclic $1,2,4$-trioxane compounds. The parameters affecting the docking results were also investigated. For the simulated annealing calculations, the moderate initial temperature $(700 \mathrm{~K})$, the very low final temperature $(0.02 \mathrm{~K})$, and the temperature reduction rate of 0.90 were suggested. The small grid spacing $(0.40 \AA$ ) and the moderate grid size $\left(20 \times 20 \times 20 \AA^{3}\right)$ are recommended for the grid-based energy evaluations. From the docking results of all 32 derivatives of tricyclic 1,2,4-trioxane compounds interact with heme molecule mainly at the endoperoxide linkage as in artemisinin. ${ }^{77}$ Therefore they confirm the same mechanism of action as artemisinin. The most occurring configurations in most tricyclic 1,2,4-trioxane compounds have $\mathrm{O}_{1}$ pointing toward the heme iron. In exception, compounds 16-21 have the most occurring configurations with $\mathrm{O}_{2}$ pointing toward the heme iron. From the results, we can conclude that the binding between tricyclic 1,2,4-trioxane compounds and heme is controlled by the steric effect at $\mathrm{C}_{3}$ position $\left(\mathrm{R}_{1}\right)$ for compounds 1-15, by steric effect at $\mathrm{C}_{12}$ position $\left(\mathrm{R}_{4}\right)$ for compounds 16-21, by both steric effect at $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$ and electrostatic effect for compounds 22-24 and by only electrostatic effect for compounds 25-32. Moreover, the dock parameters such as binding energy, $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $\mathrm{O}_{2}-\mathrm{Fe}$ distance and $\mathrm{O}_{13}$ - Fe distance of 32 derivatives of tricyclic 1,2,4-trioxane compounds were used to find the correlation
with the antimalarial activities, however, no significant relationship was found. Therefore, it seems that, the dock information is possibly not sufficient to explain the activities of these compounds and additional information from other methods should be considered together.

## CHAPTER 7

## CONCLUSIONS

Quantitative Structure Activity Relationship (QSAR) approaches have been applied to investigate the structure requirements of antimalarial activity of tricyclic 1,2,4trioxane compounds by means of classical QSAR (2D-QSAR), CoMFA (3D-QSAR), automated molecular docking using the simulated annealing monte carlo simulations. The optimized geometries based on the ab initio method at the HF/3-21G level of theory has been utilized to calculate electronic and molecular properties of compounds.

In the classical QSAR and CoMFA techniques, the whole set of compounds were used to derive the model because the number of compounds in each group is small and not sufficient to divide into training set and testing set for establishing the model for each group and predicting the compounds. The obtained models provide a good relationships between activities and molecular properties with rather high predictive power.

The information obtained from both classical QSAR and CoMFA provides some suggestions on the structural modification of tricyclic 1,2,4-trioxane compounds to increase the antimalarial effects as the following;
(1) The substituent group at the $C_{3}$ position $\left(R_{1}\right)$ especially alkyl group is not preferred. However when it is replaced by phenyl substituent group, the activity is enhanced.
(2) The small steric substitution at the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$ and the highly positive charge at the first carbon atom of substituent group connected to the $\mathrm{C}_{4}$ position $\left(\mathrm{R}_{2}\right)$ are required to improve the binding potency.
(3) The substituent group at $\mathrm{C}_{8 \mathrm{a}}\left(\mathrm{R}_{3}\right)$ and $\mathrm{C}_{12}\left(\mathrm{R}_{4}\right)$ should cause $\mathrm{C}_{8 \mathrm{a}}$ and $\mathrm{C}_{12}$ more positive charges, or another word the electron withdrawing substituent group at those positions are conductive to the activity.
Besides the 2D-QSAR and CoMFA results that giving information on relationship between structures of ligands and biological activities, docking experiments were performed to predict the interaction parameters of tricyclic 1,2,4-trioxane with the inhibition binding site of heme. Docking of the compounds revealed a consistent set of
recurring binding modes i.e. the $\mathrm{O}_{1}$ of compounds pointing toward heme iron with the $\mathrm{O}_{1}$-Fe distance in the range of $1.84-2.27 \AA$ which is comparable to artemisinin derivatives, except compounds 16-21 containing substituent at the $\mathrm{C}_{12}$ position $\left(\mathrm{R}_{4}\right)$ have $\mathrm{O}_{2}$ approach heme iron with the $\mathrm{O}_{2}$-Fe distance in the range of 1.84-2.03 $\AA$. Thus, the binding of heme and tricyclic 1,2,4-trioxane could be mainly described by interaction between heme iron and peroxide oxygen(s) as in artemisinin, hence, the same mechanism of action. The different approach to oxygen atom of peroxide linkage of compounds 1621 may result from the S and $\mathrm{SO}_{2}$ in the substituent group compare to the other compounds that contain only carbon and hydrogen atoms. The reasons possible due to the different mechanism of action or parameters for sulfur(S) from Amber force field obtained from amino acid of protein may not suitable for this docking calculation. In order to support the QSAR studies, docking parameter e.g. binding energy, $\mathrm{O}_{1}-\mathrm{Fe}$ distance, $\mathrm{O}_{2}$-Fe distance were used to correlate with antimalarial activities, however the good relationship could not be achieved. One explanation might arise from the diverse substituents of the compounds.

The combination of ligand-based (classical QSAR and CoMFA) and structuralbased design (molecular docking) results give better insights into the structural features requirements of tricyclic 1,2,4-trioxane compounds for NF54 strain and the importance of peroxide bridge in the mode of action of these derivatives. These results could provide a basis guideline to design and develop new compounds with higher activities.

## Further Work

Several improvement are possible:

1) If number of compounds is large enough, it is recommended to classify all compounds into groups according to their structural similarity.
2) Other techniques such as Molecular Dynamics simulation (MD) may show how inhibitor interact with receptor in solution phase.

## CURRICULUM VITAE

## Koonwadee Ratanasak

## Proceedings and Conferences

1. Koonwadee Ratanasak, Vudhichai Parasuk, Sirirat Kokpol, "Automated Docking Calculations of $1,2,4$-Trioxane Derivatives to Heme", The $10^{\text {th }}$ Annual Scientific Symposium of Faculty of Science, Chulalongkorn University, March, 20-22, 2002, Faculty of Science, Chulalongkorn University, Bangkok, Thailand.
2. Koonwadee Ratanasak, Somsak Tonmunphean, Vudhichai Parasuk, Sirirat Kokpol, "The Study of Interaction Between 1,2,4-Trioxane Derivatives and Heme by Docking Calculations", $28^{\text {th }}$ Congress on Science and Technology of Thailand (STT28), October, 24-26, 2002, Queen Sirikit National Convention Center or QSNCC, Bangkok, Thailand. 02-21-P.
3. Koonwadee Ratanasak, Somsak Tonmunphean, Vudhichai Parasuk, Sirirat Kokpol, "Automated Docking Calculation of 1,2,4-Trioxane Derivatives to Heme", International Conference \& Exhibition on Pure and Applied Chemistry 2002 (PACCON 2002), 29-31 May 2002, Amari Watergate Hotel, Bangkok, Thailand, 31-BCDD-11, p.121.
4. Koonwadee Ratanasak, Somsak Tonmunphean, Vudhichai Parasuk, Sirirat Kokpol. "Automated Docking Calculations of 1,2,4-Trioxane Derivatives to Heme", The Sixth Annual National Symposium on Computational Science and Engineering (ANSCSE6), April, 3-5, 2002, Walailuk University, Nakhon Sri Thammarat, Thailand.
5. Koonwadee Ratanasak, Somsak Tonmunphean, Vudhichai Parasuk, Sirirat Kokpol. "Binding of 1,2,4-trioxane compounds to heme and its relation with antimalarial activity", The Seventh Annual National Symposium on Computational Science and Engineering (ANSCSE7), March, 24-26, 2003, Chulalongkorn University, Bangkok, Thailand.
6. Koonwadee Ratanasak, Somsak Tonmunphean, Vudhichai Parasuk, Sirirat Kokpol. "Three-Dimensional Quantitative Structure-Activity Relationship (3D-QSAR) Studies of Antimalarial Tricyclic 1,2,4-trioxanes", $29^{\text {th }}$ Congress on Science and Technology of Thailand (STT29), October, 20-22, 2003, Golden Jubilee Convention Hall, Khon Kaen University, Khon Kaen.
