5273847923 : MAJOR PETROCHEMISTRY

KEYWORDS : POLYDIACETYLENE / SENSORS / RGB / THERMOCHROMISM
/ PHOTOCROMISM / SOLVATOCHROMISM / HUMIDITY

WATCHARIN NGAMPEUNGPIIS : PREPARATION OF MULTI-PURPOSED
PAPER INDICATORS FROM DIACETYLENE LIPIDS. ADVISOR : ASSOC.
PROF. MONGKOL SUKWATTANASINITT, Ph.D., CO-ADVISOR :
GAMOLWAN TUMCHARERN, Ph.D., 138 pp.

Diacetylenes with β -alanine ethyl ester and di- β -alanine ethyl ester were synthesized by amide coupling method using EDC and HOBt as coupling reagents. The diacetylene were fabricated onto filter paper and polymerized by 254 nm UV light. The prepared devices were intended to be used as indicators *i.e.* UV-dose, temperature, solvent and humidity indicators. The color transitions of the indicators were determined from their color images using the RGB color system in which the crossing point of %B and %R curves from their plots against the independent variables such as time and temperature. The sensitivity of UV and temperatures can be tuned by converting carboxylic acid head group to β -alanine ethyl ester and di- β -alanine ethyl ester and varying the number of aliphatic chain length. Comparing between different functional groups, the thermal sensitivity was not always in line with the UV sensitivity that demonstrated other mechanisms beyond the photo-induced thermochromism for the blue-to-red color transition induced by UV light. The attempt in constructing an indicator array from 6 PDAs for detection and classification of organic solvents gave relatively low classification accuracy of 74%. The diacetylene carboxylic acid could be used as humidity sensing materials via an alkalinochromism effect by a zone coating of the diacetylene and K_2CO_3 . The blue PDA zone turned red at 62% RH with time dependence starting from the PDA/ K_2CO_3 interface at 3 h and completed within 24 h. This time dependent colorimetric transition is very attractive for real applications where the moisture-protected products are usually unintentionally exposed to the ambient humidity for an unknown period of time.

ACKNOWLEDGEMENTS

I would like to express my appreciation to my advisor, Associated Professor Dr. Mongkol Sukwattanasinitt and my co-advisor Dr. Gamolwan Tumcharern for their invaluable suggestion, generousness and extremely encouragement during the course of this research. This research is impossible to succeed without their helpfulness. Moreover, I have learned many things from my advisor such as attitude, creativeness, logic and kindness to students. He supported me to do the things that gave me the new experiences such as going to research in Japan, attending the Sci & Tech initiative and Sustainability contest until getting the award. I appreciate him and I try to remember to the things that he taught me for using in my life.

I would like to show gratitude to Assistant Professor Dr. Warinthorn Chavasiri, chairperson of dissertation defense committee, for their kind attention and recommendations. I also would like to thank Assistant Professor Dr. Paitoon Rashatasakhon, Assistant Professor Dr. Sumrit Watcharasindhu and Dr. Anawat Ajavakom for his attention and suggestion during our group meeting.

I would like to express my sincere gratitude to Dr. Prompong Pienpinijthum from Sensor Research Unit, Department of Chemistry, Faculty of Science, Chulalongkorn University for SEM data.

My appreciation is also given to many people in our research group; Dr. Warathip Siripornnoppakhun for PCA data and valuable advice, Mr. Chaiwat Phollookin and Dr. Thirawat Sirijindalert for training and suggestion in this research; Miss Kanokthorn Boonkitpattarakul and Miss Nattaporn Kimpitak for their helpfulness; and everyone in MAPS Group for a great friendships and encouragement;

I would like to thanks Chulalongkorn University and my financial support from the Thailand Graduate Institute of Science and Technology (TGIST) from NSTDA.

Finally, I would like to express my thankfulness to my beloved parents who always stand by my side during both of my pleasant and hard time.

CHAPTER I

INTRODUCTION

1.1 Background and statements of problems

Due to their unique optical and electrical properties associated with extensively delocalized π -electron networks and intrinsic conformational restrictions, conjugated polymers have been widely investigated for applications as indicators and sensors for detection of environmental condition. Particularly, their change of electronic absorption and emission properties have been gracefully applied to the design of efficient sensors [1,2].

Polydiacetylene (PDA) is a promising class of conjugated polymer successfully used as many sensors. PDAs can be produced by UV or γ -irradiation of crystalline or semicrystalline states obtained from molecular self-assembled diacetylene (DA) monomers without the need for chemical initiators or catalysts. The polymers possess unique colorimetric properties useful for sensing applications. Various types of stimuli such as temperature, organic solvent, mechanical stress, molecular recognition, pH and UV light can cause color change of PDAs. The color transition property can be tuned via rational design of supramolecular interactions among the polymeric side chains [3-5] PDAs have also been prepared in the forms of various nanostructures such as vesicles, tubes, and ribbons [6-11]. The formation of nanovesicles allows the preparation of homogeneously dispersed PDA vesicle sols resulting in several noteworthy chemical and biological sensing systems [12]. However, the aqueous sols have short shelf life and are not suitable for portable and tag-on applications. Fabrication of PDAs as solid state sensors or indicators in the form of gel [13] thin film [14,15] and electrospun fiber [16] have recently been reported. The preparation methods for these forms of PDAs generally require additional polymer matrix and equipment setup. Recently, white paper has been demonstrated as a very promising supporting material for portable and disposable multi-sensing devices because it is omnipresent, inexpensive and easy to be stored, transported and handled [17,18]. In our research group, we have also recently reported

the use of filter paper as a support for fabrication of PDA based colorimetric sensors of solvents, surfactants and VOCs [19-21].

UV-Vis absorption measurement is a common method for determination of colorimetric response percentage (%CR) for solution samples [9,15,22] but this technique does not generally give reliable values for opaque solid materials. CCD imaging technology has turned photography into a readily processable digital form [23]. The capability to capture wide area of image of digital imaging is also the advantage, in comparison with the reflective spectroscopic instrument, that produce more reliable color analysis of rough surface samples such as paper. For examples, it has recently been used along with the RGB color system to record and evaluate colorimetric sensors [17] including PDA films [19-21,24-25]. Despite these successes in quantifying colorimetric responses of solid state PDAs, there has not yet been proposition of the degree of color change that should represent the color transition point of PDA. In this research, a utilization of webcam and RGB values to quantify the color transition PDAs on paper support along with mathematical formula to use RGB values in specifying the color transition temperatures PDA paper based indicators. The technique developed in this work should provide practical guidelines for systematic and comparison of chromic properties of PDAs toward the development of economical and reliable multi-purposed paper indicators from diacetylenes.

1.2 Theory

1.2.1 Polydiacetylene

A polydiacetylene (PDA) is an ene-yne conjugated polymer comprising of double and triple bonds in its backbone. It can be prepared by a topological 1,4-addition polymerization of diacetylene monomer by UV light or γ -rays as shown in Figure 1.1.

Figure 1.1 Phototopolymerization of diacetylene monomers. [26].

Topological polymerization is a polymerization which requires specific prealignment of the monomer usually found in solid state crystal [27]. For topological polymerization of diacetylenes, the distance (d) between the corresponding tripple bonds of the adjacent monomers and the orientation angle (θ) relative to the translation axis should be $\sim 5 \text{ \AA}$ and $\sim 45^\circ$, respectively [28-29].

1.2.2 Polydiacetylene forms

There are numerous forms, which PDA can be structured: bulk single crystal, Langmuir monolayer film, multilayer film, nano tube and vesicle.

1.2.2.1 Polydiacetylene vesicles

The vesicle is one of the most widely used forms of polydiacetylene for sensor applications. It is water filled spherical assembly of lipid bilayer. The formation of vesicle is thermodynamically driven so that the hydrophobic surface of the lipid molecules is not exposed to water. Only the hydrophilic head group of the lipid is exposed to water inside and outside of the bilayer membrane. A number of lipids containing diyne unit can self assemble into vesicle that have the right packing parameters for topological polymerization to form PDA vesicles (Figure 1.2). In the form of vesicle, PDA can be homogeneously dispersed in an aqueous media to form a sol type colloid, which is convenient for further characterization, fabrication and applications. The most studied diacetylene lipids are 10,12-pentacosadiynoic acid

(PCDA). The interest in these lipid vesicles is mainly related to the development into bio- [30] and chemosensors [31].

Figure 1.2 Structure and formation of a PDA lipid vesicle.

1.2.2.2 Polydiacetylene films

It is widely accepted that the sensing process of PDA of diacetylene lipids is initiated at the lipid head group. Intuitively, the most desirable form of PDA for sensing applications is thin film as it can maximize sensing area and it is easy to be developed into simple to use device. Several techniques have been utilized for making different types of thin films on the surface of substrates.

Langmuir-Blodgett film can generate an ideal highly ordered monolayer assembly of lipid molecules at water/air interface. The monolayer can be transferred onto solid substrate by horizontal or vertical deposition (Figure 1.3). The monolayer Langmuir-Blodgett film is however often fragile and difficult to prepare in large area. The number of layers can be increased by repeating the transferring process with a newly generated monolayer. Hence, it can be quite bothersome to prepare a multilayer film as the preparation of each new monolayer requires a slow surface compression and the transferring step needs adroit attention. This type of PDA film is one of the most interesting form of PDA in research but the development of the technique for practical mass production remains elusive [32].

Figure 1.3 Preparation of Langmuir Blodgett film a) floating of condensed monolayer film on the water subphase, b) film deposition, c) monolayer films on the substrate.

1.2.2.3 Polydiacetylene electrospun fibers

Electrospinning has proved to be an efficient method for forming long polymer fibers with diameters in the range from nanometers to several micrometers as shown in Figure 1.4. In this technique, a high voltage is applied to a conductive capillary attached to a reservoir containing a polymer solution as shown in Figure 1. A charged polymer jet is ejected from the surface of the polymer solution when the charge imbalance exceeds the surface tension of the polymer solution. Polymer fibers are formed when the jet stream, driven by the electrostatic force, moves to the grounded screen collector [33].

Figure 1.4 A schematic representation of the preparation of polymer fibers embedded with PDA supramolecules using the electrospinning technique, followed by irradiation with UV light.

1.2.3 Colorimetric properties of polydiacetylene

PDA usually appear as deep colored materials that exhibit interesting colorimetric properties. Optical absorption in polydiacetylene occurs via an electronic $\pi \rightarrow \pi^*$ transition within the linear π -conjugated polymer backbone. Upon polymerization, frequently the first chromogenically interesting state of PDA appears blue in color. The exposure of PDA to environmental perturbations, such as temperature, UV light, pH, solvent, mechanical stress and ligand-receptor interactions, induce a significant shift in absorption from low to high energy bands of the visible spectrum, so the polydiacetylene transforms from blue ($\lambda_{\text{max}} \sim 630 \text{ nm}$) to red ($\lambda_{\text{max}} \sim 540 \text{ nm}$). These perturbations alter the polymer side chain orientation that in turn change the backbone strain and torsion, thus changing the electronic states and the corresponding optical absorption.

The most investigated PDAs are those having blue color, which can change their color to red corresponding to the shift of the maximum absorption peak from as a result of reduction of the effective conjugation length. The color transition can be induced by several external stimuli

1.2.3.1 Colorimetric Response (CR)

The color transition of the polymerized vesicles was monitored by measuring the absorbance differences between the vesicles before and after stimulation by an interesting parameter. This information is often converted to a percentage, termed the Colorimetric Response (CR) [34].

A quantitative value for the extent of blue-to-red color transition is given by the colorimetric response (%CR) which is defined as

$$\%CR = (PB_0 - PB) / PB_0 \times 100$$

Where $PB = A_{\text{blue}} / (A_{\text{blue}} + A_{\text{red}})$, A_{blue} and A_{red} are the absorbance of the blue and the red phase at 630 and 540 nm, respectively. The visible absorbance was measured by a temperature controlled UV-vis spectrometer. PB_0 is the initial percent blue of the vesicle solution and film before heated. All blue-colored PDA vesicle solution and film samples were heated from 10 to 90 °C.

1.2.4 RGB color model

According to development of paper based colorimetric respond of polydiacetylene is a simple method and suitable to use as a sensors application, since evaluate the results into a quantitative analysis can be collected by using the RGB color model. The RGB color model is an additive color model in which red, green, blue color are added together in various component ratio to reproduce a broad array of colors as shown in Figure 1.5. The name of the model comes from the initials of the three additive primary colors, red, green, and blue. The main purpose of the RGB color model is for the sensing, representation, and display of images. The RGB color model was used to describe how much of each red, green, and blue color is included in the photographic images [35].

For the basic of the RGB value(R, G, B), the color is black when the intensity of each component is zero (0, 0, 0) and the color is white when the intensity of each component is full (255, 255, 255). When the intensities are the same, the result is a shade of gray, darker or lighter depending on the intensity.

The RGB color model.

1.3 Literature surveys on applications of polydiacetylenes

1.3.1 Thermochromism

Thermochromism, the color transition upon the increase of temperature, is one of the interesting chromic properties of polydiacetylenes both for its applications and fundamental understanding. Thermochromism in polydiacetylenes arises from the conformational changes of the conjugated backbone from planar to non-planar due to movement of the side chains. The color transition is thus resulted from the increase of energy gap between the HOMO and LUMO level. The color transition of polydiacetylenes is driven by the relief of mechanical strain in their structures [36].

For polydiacetylene vesicles, hydrogen bonding between the head groups of the lipid monomers is usually responsible for the planarity of the conjugated backbone. Thermal energy can break or weaken the hydrogen bonding between the head groups resulting in random movement of the side chains and lower the planarity of the backbone and hence the average conjugation length of π -electrons along the polymer backbone inducing the color change from blue to red.

In 1998, Okada *et al.* [9] studied the self-assembly in vesicles form of diacetylene containing carboxylic in hydrophilic head group and its derivatives which various alkyl chain length within the chain and between diacetylene and carboxyl group (Figure 1.6) in water media. Then polymerized by UV-irradiation 254 nm and studied the thermochromic properties monitoring by UV-vis spectrometer. It was found that polydiacetylene which have the short alkyl chain length between diacetylene and carboxyl group (compound 3 and 4) were more sensitive to the thermal changes than long alkyl chain length (compound 1 and 2).

Figure 1.6 Structure of diacetylene monomers used in investigations of thermochromism in vesicles.

In 2005, Kim *et al.* [26] reported the colorimetric reversibility of polydiacetylene supramolecules, derived from a variety of functionalized diacetylenic lipids as shown in Figure 1.7. Polydiacetylene vesicles prepared from PCDA-mBzA 1, bearing terminal m-carboxyphenylamido groups. They studied the effects of (1) internal amide groups, (2) headgroup aromatic interactions, (3) lengths of the hydrophobic alkyl chains, and (4) terminal carboxylic groups on the colorimetric reversibility of polydiacetylene. The results demonstrate that well developed hydrogen-bonding and aromatic interactions between headgroups are essential for complete recovery of the length of the conjugated π -electron chain following thermal stimulus.

Figure 1.7 Structures of diacetylene lipids investigated for thermochromism.

In 2007, Fujita *et al.* [37] proposed that molecular modeling to seek a stable conformation of PDA prepared from Gns in the gel state which is useful in predicting the effective conjugation length (ECL) in PDA where the odd-even number of alkyl

chains (n) is a key factor for determining the blue and red phases of the PDAs (See in Figure 1.8).

Figure 1.8 Chemical structure of G_n and the optimized conformation of 24 mers of (upper) poly G_3 and (lower) poly G_4 .

In 2010, Wacharasindhu *et al.* [4] synthesized Mono- and diamides derivatives of 10, 12-pentacosadiynoic acid (PCDA) from condensation of PCDA with various aliphatic and aromatic diamines. The color transition temperatures and thermochromic reversibility of the polymers are varied depended on the number of amide groups and the structure of the aliphatic and aromatic linkers. The phenylenediamide and polymethylenediamide PCDA derivatives give polydiacetylenes with complete thermochromic reversibility, while the polydiacetylenes obtained from 1,2-cyclohexylene and glycolic chain diamide derivatives exhibited irreversible thermochromism, whereas the polymers attained from the aromatic monoamide analogues are partially reversible. The variation of the linkers also allows the color transition temperature of the polydiacetylene to be tuned in the range of 20°C to over 90°C (See in Figure 1.9).

Figure 1.9 Color of PDA sols recorded by photography during the heating process displaying the variation of color transition temperature.

In 2010, Phollookin *et al.* [5] investigated a series of bisdiynamide lipids containing various lengths of methylene spacer ($m=2, 3$ and 4) between the diynes and the diamide headgroup and number of methylene units ($n = 6$ and 9) in their hydrophobic tails are synthesized. The color transitions from blue to red during heating-cooling cycles of the PDA sols are photographically recorded and monitored by UV-vis absorption spectroscopy. The bisdiynamide PDAs exhibit excellent thermochromic reversibility and the color transition temperature can be tuned between $25-55$ °C by the variation of m and n values as shown in Figure 1.10. The decrease of n value enhances the thermal sensitivity resulting in lower color transition temperature, the effect of m value is not as straightforward. Moreover, temperature indicators can be obtained by applying a screen printing ink formulated from the bisdiynamide monomer on plastic substrates followed by UV irradiation to generate desired patterns of thermochromically reversible PDAs.

Figure 1.10 Structure of diacetylene monomers, their color transition and reversibility in vesicles solution.

In 2012, Ampornpun *et al.* [38] reported that two series of symmetrical (S_x) and unsymmetrical (U_y) diacetylene monomers containing diamide groups with different methylene units are successfully prepared (See in Figure 1.11). Photopolymerization of their nanovesicles dispersed in water is carried out by irradiation at 254 nm affording blue sols of the corresponding PDAs. The degree of thermochromic reversibility (%DR) of the PDA sols are determined using UV-vis spectroscopy in order to probe effects of the number of the methylene units, x and y , within the linker and hydrophobic tail, respectively. The complete color reversibility (%DR > 89%) is observed only when x is an even number while partially reversible or irreversible thermochromism (%DR < 65%) is displayed in the case of odd x number. For the U_y series, the color recovering ability within the heating and cooling process increases along with the y number; %DR = 3, 62, and 90% for $y = 0, 4$, and 16, respectively. This work is the first direct demonstration of the roles of number of methylene units within the diacetylene monomers on the thermochromic reversibility of their PDAs that provide additional dimensions for rational molecular design in the development of PDA thermal sensors.

Figure 1.11 Structure of investigated diacetylene monomers: symmetrical diyndiamides (S_x) and unsymmetrical diyndiamide monomers (U_y).

In 2013, Chanakul *et al.* [39] reported polydiacetylene (PDA)/ZnO nanocomposites are prepared by using three types of monomers with different alkyl chain length, 5, 7-hexadecadiynoic acid, 10, 12-tricosadiynoic acid, and 10,12-pentacosadiynoic acid. The monomers dispersed in aqueous medium spontaneously assemble onto the surface of ZnO nanoparticles, enhanced by strong interfacial interactions. All nanocomposites show reversible blue/purple color transition upon multiple heating/cooling cycles, while the irreversible blue/red color transition is observed in the systems of pure PDAs (Figure 1.12). The shortening of alkyl side chain in PDA/ZnO nanocomposites leads to a systematic decrease in their color transition temperatures.

Figure 1.12 Color photographs of the aqueous suspensions of (a) pure poly(PCDA), (b) poly(PCDA)/ZnO nanocomposite, (c) pure poly(TCDA), (d) poly(TCDA)/ZnO nanocomposite, and (e) poly(HDDA)/ZnO nanocomposite taken upon increasing temperature from 30 to 90 °C, followed by cooling to room temperature.

1.3.2 Photochromism

Photochromism were chromic properties that material can change color by irradiation of UV light or γ -rays. The mechanism of color transition of PDA by photo is not clear. There are groups of diacetylene monomer had affect on the colorimetric transition as reported by several researchers.

In 1985, Kanetake *et al.* [40] investigated the change of absorption spectra by UV light irradiation (photo-chromism) and by thermal annealing (thermo-chromism) have been investigated on vacuum-deposited polydiacetylene (12-8 PDA) films. The

results are compared with those of the Langmuir-Blodgett films of the same 12-8 PDA. It is suggested that the blue-to-red colour conversion of these films is associated with a isomeric transformation of the polymer backbone structures. The films also show a remarkable colour change by a visible laser-beam irradiation.

In 1987, Tokura [41] reported that the photoinduced change in absorption spectra has been measured on poly(10, 12-pentacosadiynoic acid) (PDA-12,8) films for various photon energies and light intensities. The observed photochromic behaviors indicate that photoexcited electron-hole pairs in polymer backbone chains relax into a metastable state which develops into clusters with a local change in bond structure via a temperature independent and self-activated multiple excitation process produced by light irradiation.

In 1989, Wenzel and Atkinson [42] investigated that the thermochromic and proposed visible photochromic properties of poly(10, 12-pentacosadiynoic acid) (PDA-12,8) are examined by resonance Raman (RR) and Fourier transform infrared (FTIR) spectroscopies. Irradiation at 532 nm of water-cooled (0.5 °C) samples of the blue-colored material produces no chromatic changes. A chromatic change to the red-colored material is induced by 532-nm radiation, however, when the PDA-12,8 is not cooled. No evidence supporting a visible photochromic change in PDA-12,8 is found, and it is proposed that the previously reported chromatic properties derive from thermal effects. RR results also show that no change occurs in the distribution of electron density along the PDA-12,8 backbone when chromatic effects are induced.

In 1997, Peng [43] investigated the photochromism in polydiacetylene crystals. It is considered that the photochromism is the result of phase structural conversion during photoexcitation excitonic relaxation process, and its dependence on the energy and density of incident photons can be explained correctly. They claimed that the electronic excitation state is unaffected by localized heating of laser irradiation. If this conversion is mainly caused by localized heating, the change of color will spread to surrounding nonirradiated region because of very high thermal conductivity of polydiacetylene crystals.

In 1999, Huo *et al.* [44] studied a new diacetylene compound (PDATAZ), which readily formed a complementary hydrogen bonding self-assembly at the air-water interface or in the solid state with barbituric acid (BA) or cyanuric acid (CA). It

was found that the chromatic property of polydiacetylenes is determined by whether the polymer chain is capable of adopting a linear chainlike shape. With the continuous increase of the length of the polymer chain, the original linear polyenyne backbone starts to “self-fold” to a “zigzag” structure due to the free rotation of single bonds within the polymer chain. The efficient π -electron delocalization along the polyenyne backbone is interrupted by this process, leading to a chromatic change from the blue to red form of polydiacetylenes. If there are strong intermolecular interactions existing between the polar groups of the side chains, such as the complementary hydrogen-bonding network between the triaminotriazine (TAZ) moiety of the diacetylene amphiphile and its complementary components, the movement of the side chains is restricted and the folding process of the polymer backbone is inhibited. The polymer backbone is able to maintain its extended chainlike conformation, leading to only the blue form absorption band.

In 2004, Song *et al.* [45] reported the design, preparation, and characterization of self-assembling functional bolaamphiphilic polydiacetylenes (BPDAs) inspired by nature’s strategy for membrane stabilization. The conjugated polymers can be engineered to display a range of radiation-, thermal-, and pH-induced colorimetric responses (Figure 1.13). They observed dramatic nanoscopic morphological transformations accompanying charge-induced chromatic transitions, suggesting that both side-chain disordering and main-chain rearrangement play important roles in altering the effective conjugation lengths of the poly(ene-yne).

Figure 1.13 Radiation dose-induced colorimetric response of BPDAs: BPDA-1 (green triangle); BPDA-2 (pink circle); BPDA-3 (blue diamond); BPDA-4 (red square). Error bars indicate the standard deviation of six replicate experiments.

In 2006, Yuan *et al.* [46] revealed that a photoinduced chromatic transition from blue to red for the polydiacetylene 10, 12-pentacosadiynoic acid produces an obvious change in the ultraviolet–visible absorption and fluorescence emission spectra. A two-dimensional micropattern has been realized on the basis of this change and imaged with a confocal fluorescence microscope. The results indicate that the conformational change of alkyl side chains constricted by hydrogen-bonded head groups imposes strain on the polymer backbone and finally leads to a drastic decrease in the π -electron-conjugation length.

In 2010, Sung *et al.* [47] reported highly ordered lamellar polydiacetylene nanocomposites synthesized by assembling polydiacetylene and azobenzene through a ready solution process. The trans-to-cis transition of azobenzene under UV light may induce a conformation change of PDA with color changes through pulling on its side chains as shown in Figure 1.14. Lengths of the side chains play a critical role for the transfer efficiency of the conformation change from azobenzene to PDA.

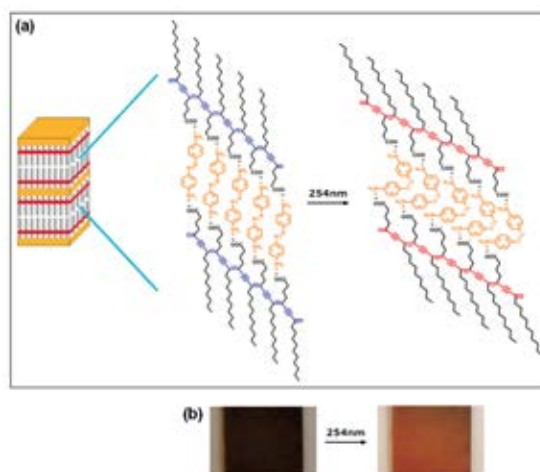

Figure 1.14 PDA nanocomposite films with ordered lamellar mesostructure derived from 4,4'-azodianiline and 5,7-octadecadiynoic acid. (a) Schematic illustration of trans-to-cis transition in azobenzene under UV irradiation and chromaticism of complexed PDA. (b) Photographs of blue and red films during the above process.

1.3.3 Solvatochromism

Solvatochromism is the ability of a chemical substance to change color due to a change in solvent polarity. The molecularly ordered states of supramolecular PDAs

can be influenced also by the presence of organic solvents as investigated by many researchers.

In 2007, Kim *et al.* [31] have developed the efficient sensors for the detection of volatile organic compounds (VOCs) based on conjugated polymer-embedded electrospun fibers. The observation of an organic solvent induced, blue-to-red color transition of PDA embedded electrospun fibers suggests that the colorimetric response might vary in an organic solvent-dependent manner on the structure of diacetylene monomer. They show different colorimetric responses upon exposure to the 4 organic solvents such as chloroform, tetrahydrofuran (THF), ethyl acetate (EA), or *n*-hexane as illustrated in Figure 1.15.

Figure 1.15 Photographs of the PDA-embedded electrospun fiber mats prepared with diacetylene monomers 1-4 after exposure to organic solvent.

In 2008, A. Potisatityuenyong and co worker [3] conducted extensively investigation poly-10,12-pentacosadiynoic acid (poly(PCDA)) vesicle solution in the aspect of thermochromism, solvatochromism and alkalinochromism. In the case of solvatochromic and alkalinochromic experiment, UV-vis absorption and observation by eye show the similar pattern, blue to red color transformation. The decreasing and increasing in absorbance of red and blue phase without peak shifting indicate directly to quantitative conversion between blue and red vesicle. Solvatochromism and alkalinochromism involve hydrogen bond breaking turning the blue vesicle into red color. The author proposed the mechanism of color transition of PCDA as shown in Figure 1.16.

Figure 1.16 Proposed side-chain movements in the chromic transitions of poly(PCDA) vesicles upon organic solvent.

In 2009, Yoon *et al.* [48] have generated the electrospun fiber mats from PDA-embedded polymer matrix that can be used to detect volatile organic compounds (VOCs). The results display the different color patterns of the fiber mats derived from different combinations of PDA-ABA 1 and PCDA-AN 2 as illustrated in Figure 1.17.

Figure 1.17 Schematic representation of the preparation of PDA-embedded electrospun microfibers and photographs of the polymerized PDA-embedded electrospun fiber mats after exposure to organic solvents at 25 °C for 30 s.

In 2010, H. Jiang and colleagues [49] have also reported the development of a novel polydiacetylene (PDA)-based sensitive colorimetric microarray sensor for the detection and identification of volatile organic compounds. PDA-embedded polymer matrix films as the multi-layer PDA-based micro patterns (Figure 1.18) could be prepared by the spin-coating method combined with the sol-gel process. Polydimethylsiloxane Sylgard 184 (PDMS) was employed to enhance the stability of the PDA films when dipped in VOCs, especially chlorinated solvent.

Figure 1.18 photographs of the PDA-embedded polymer matrix films derived from TCDA, PCDA, PAPCDA and CNAPCDA after dipped in organic solvents at room temperature.

In 2010, S. Wu and colleagues [50] investigated the effects of solvents on structure of micelle-like assemblies of an azo chromophore-functionalized polydiacetylene (polyAzoDA) and polymerized tricosanoic acid (polyTDA). They used the mixtures of water with glycol, DMSO, ethanol and THF to observe blue-to-red color changes of polydiacetylenes. They found that the colors of polyTDA and polyAzoDA change at certain contents of organic solvents. The results in Figure 1.19 exhibit the strength of the polyTDA-solvent interaction in the following order: THF>ethanol> DMSO>glycol. According to the results, THF is a solvent which can effected on blue-to-red color transitions of polyAzoDA in THF/water mixtures. However, they do not observe color transitions in the other solvents/water mixtures. The authors have proposed that the stability to several solvents of polyAzoDA caused by the H- and J-like aggregates of azo chromophores in polyAzoDA.

Figure 1.19 Photographs of micelle dispersions in different water-solvent mixtures. At increasing solvent content, the color of (a) polyTDA and (b) polyAzoDA changes from blue to purple/red depending on type of solvent and its relative content, respectively.

In 2011, Pumtang et al. [19] reported the synthesis of a novel series of diacetylene acids from the condensation of pentacosylamine (PCDAmine) and dicarboxylic acid or its anhydrides. One of these diacetylene lipids, 4-(pentacosylamino)-4-oxobutanoic acid (PCDAS), is used in combination with pentacosylnoic acid (PCDA) for dropcasting on pieces of filter paper which are consequently irradiated by UV light to generate a paper based sensor array for solvent detection and identification. Upon the exposure to various types of organic solvents, the blue colored sensors colorimetrically respond to give different shades of colors between blue to red (Figure 1.20). The color patterns of the sensor array are recorded as RedGreenBlue (RGB) values and statistically analyzed by principal component analysis (PCA). The PCA score plot reveals that the array is capable of identifying eleven common organic solvents.

Figure 1.20 Array of cropped photographic images of PDAs on filter paper fabricated from PCDA and PCDAS responding to various organic solvents.

In 2012, Eaidkong *et al.* [21] reported detection and identification of VOCs by paper-based polydiacetylene (PDA) colorimetric sensor array. They were prepared from eight diacetylene monomers, six of which are amphiphilic and the other two are bolaamphiphilic. To fabricate the sensors, monomers are coated onto a filter paper surface using the drop-casting technique and converted to PDAs by UV irradiation. The PDA sensors show solvent induced irreversible color transition upon exposure to VOC vapors as shown in Figure 1.21. When combined into a sensing array, the color change pattern as measured by RGB values and statistically analyzed by principal component analysis (PCA) is capable of distinguishing 18 distinct VOCs in the vapor phase. The PCA score and loading plots also allow the reduction of the sensing elements in the array from eight to three PDAs that are capable of classifying 18 VOCs.

Figure 1.21 a) Structure of diacetylene monomers b) Scanned images of the paper-based PDA sensor array prepared from 1–8 exposed to various saturated vapors of volatile organic solvents.

1.3.4 Alkalinochromism and Acidochromism

Alkalinochromism and acidochromism were chromic properties that material can change color by deprotonation in case of alkalinochromism and protonation in case of acidochromism. Either alkalinochromism or acidochromism, the role of head group of diacetylene monomer had directly impact on the colorimetric transition as reported by several researchers.

In 1998, Cheng and coworkers [51] had been synthesized and studied the colorimetric response in various pH solutions of a series of amino acid-derivatized 10, 12-pentacosadiynoic acid. The result showed a different colorimetric response based on type of head groups. For example, Glu-PDA which has dicarboxylic head group changed the color from blue to red at pH 6 by deprotonation of the carboxylic group. The protonation of the tertiary amine head group of DMAP-PDA changed its color at pH 5. His-PDA which has both of carboxylic and imidazole changed the color at pH below 0 and pH 8-9 (Figure 1.22).

Figure 1.22 a) Structure of the diacetylene lipid 10,12-pentacosadiynoic acid (**1**) and its derivatives: lipids **2-6**, amino acids derivatives; lipid **7**, 3-(dimethylamino)propylamine (DMAP) derivative. b) Schematic diagram of amino acid-derivatized polydiacetylene liposomes in a chromatic transition.

In 1999, Jonas *et al.* [59] studied a novel system based on hydrazide derivatives of single chain diacetylene lipids which are 10,12-Tricosadiynohydrazide (THY) and 10,12-Pentacosadiynohydrazide (PHY). These materials showed an unusual aggregation and polymerization behavior in organic solution, in contrast to the parent carboxylic acids. In addition, these hydrazide lipids undergo an unprecedented reversible color change (blue/red) in polymerized vesicles when the pH of the surrounding aqueous medium is cycled between acidic and basic conditions. This unusual behavior is attributed to the unique hydrogen-bonding pattern of the hydrazide head group (Figure 1.23).

Figure 1.23 Schematic representations of the polymerization behavior and colorimetric changes of the diacetylene hydrazides PHY and THY in the presence of HCl or NH_3 .

In 2011, Charoenthai *et al.* [52] investigated that the colorimetric response of the polydiacetylene (PDA) vesicles prepared by 10,12-tricosadiynoic acid (TCDA), 10,12-pentacosadiynoic acid (PCDA) and N-(2-aminoethyl)pentacosadiynamide (AEPCDA) were stimulated by temperature, ethanol and pH. They found that a shorter side chain of poly(TCDA) yields weaker inter- and intra-chain dispersion interactions in the bilayers compared to the system of poly(PCDA). The color transition of poly(TCDA) and poly(PCDA) vesicles occurred when increasing of pH to ~ 9 and ~ 10 , respectively (Figure 1.24). The poly(AEPCDA) vesicles, on the other hand, change color upon decreasing pH to ~ 0 .

Figure 1.24 a) The colorimetric responses (%CR) of the vesicles were plotted as a function of pH. Symbols are (O) poly(PCDA), (Δ) poly(TCDA) and (\square) poly(AEPCDA). b) The charged species of head groups of poly(PCDA) in high pH region and poly(AEPCDA) in low pH region.

1.3 Objectives and scope of the research

The objectives of this thesis are synthesis of diacetylene monomers containing β -alanine ethyl ester and di- β -alanine ethyl ester for use as indicator for detection of temperature, UV doses, organic solvent and humidity. To achieve the objectives, the work scopes are shown as following;

- 1) To synthesize and characterize amide and diamide derivatives from 10, 12-pentacosadiynoic acid (PCDA), 10, 12-tricosadiynoic acid (TCDA), 6, 8-nonadecadiynoic acid (NDDA) and 5,7-octadecadiynoic acid (ODDA)
- 2) To prepare polydiacetylene indicator on the filter paper
- 3) To test the sensitivity of the indicators for detection of temperature, UV doses, organic solvent and humidity.

CHAPTER II

EXPERIMENTAL

2.1 General Information

2.1.1 Chemicals and materials

1. 10,12-Pentacosadynoic acid (PCDA), GFS, USA
2. 10,12-tricosadiynoic acid (TCDA), GFS, USA
3. 6,8-nonadecadiynoic acid (NDDA), GFS, USA
4. 5,7-octadecadiynoic acid (ODDA), GFS, USA
5. Ethyl-3-aminopropanoate hydrochloride, Aldrich, Germany
6. 3-Aminopropionic acid, Fluka, Switzerland
7. 1-Hydroxybenzotriazole hydrate (HOBt•H₂O), Aldrich, Germany
8. 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC), Fluka, Switzerland
9. Diethylether (Et₂O), reagent grade, Lab-Scan, Ireland
10. Chloroform (CHCl₃), AR grade, Lab-Scan, Ireland
11. Dichloromethane (CH₂Cl₂), commercial grade, Lab-Scan, Ireland
12. Hexane, commercial grade, Lab-Scan, Ireland
13. Ethyl acetate (EtOAc), commercial grade, Lab-Scan, Ireland
14. Tetrahydrofuran (THF), AR grade, Lab-Scan, Ireland
15. Methanol (CH₃OH), commercial grade, Lab-Scan, Ireland
16. Sodium hydroxide (NaOH), Merck, Germany
17. Hydrochloric acid (HCl), Merck, Germany
18. Magnesium sulfate (MgSO₄) anhydrous, Riedel-deHaën[®], Germany
19. Silica gel 60, Merck, Germany

2.1.2 Apparatus and equipments

1. Rotary evaporator, R200, Buchi, Switzerland
2. Ultrasonicator, Elma, Germany
3. Magnetic stirrer, Fisher Scientific, USA
4. Hot plated magnetic stirrer, IKA, Germany

5. Pipette man (P20, P200 and P5000), Gilson, France
6. Pipette man (Le100 and Le1000), Nichiryo, Japan
7. Nuclear Magnetic resonance spectrometer (NMR) 400 MHz, Mercury 400, Varian, USA
8. Differential scanning calorimetry (DSC), NETZSCH DSC 204 F1, Germany
9. Scanning electron microscopy (SEM), JEOL, JEM-2100, Japan
10. Webcam, ICON228, 14M pixels
11. Labtop, Macbook pro, apple, USA
12. UV Lamp, TUV 15W/G15 T18 lamp, Philips, Holland.

2.2 Synthesis of diacetylene monomer

2.2.1 Synthesis procedure

β -Alanine ethyl ester diacetylene and di- β -alanine ethyl ester diacetylene, boc-protected β -alanine was synthesized by amide coupling synthesis [53]. β -Alanine (0.71 g, 8 mmol) was dissolved in NaOH solution (1.0 M, 20 mL) and t-butanol (10 mL) of was then added. The solution of Boc₂O in t-butanol (15 mL) was added dropwise to obtain a clear solution and was stirred for 12 h. After removing the solvent by rotary evaporator, the mixture was adjusted to pH 2 by HCl solution (2.0 M) and then extracted with ethyl acetate (5 × 25mL). The combined organic layer was separated, dried over anhydrous MgSO₄ and filtered. The filtrate was evaporated to give Boc-protected β -alanine as white powder (1.27 g, 6.69 mmol, 83% yield).

The di- β -alanine ethyl ester was prepared by first dissolving boc- β -alanine (1.50 g 7.93 mmol) and HOBt.H₂O (1.60 g, 11.91mmol) in CH₂Cl₂ (15 mL). Then, 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (EDC) (2.28 g, 11.91 mmol) in CH₂Cl₂ (20 mL) was added. The mixture was stirred for 1 h before β -alanine ethyl ester hydrochloride (1.46 g, 9.52 mmol) and triethylamine (4.40 mL) in CH₂Cl₂ (15 mL) were then added at 0 °C and stirred for 3 h. The reaction mixture was evaporated by rotary evaporator and was extracted by ethyl acetate 20 mL. The organic layer was consecutively washed by deionized water (2 × 10mL), HCl (10 mL), saturated NaHCO₃ (10 mL) and water (10 mL). The organic layer was dried by MgSO₄ anhydrous and was evaporated to obtain crude Boc-di- β -alanine ethyl ester

product (60%) as a white solid. The product was deprotected by trifluoroacetic acid after stirring for 2 h and freeze dried to give the desired di- β -alanine ethyl ester product in quantitative yield.

Ethyl 3-(pentacos-10,12-diynoylamido)propanoate (EPCDP): 10,12-Pentacosadiynoic acid (0.38 g, 1.0 mmol) and 1-hydroxybenzotriazole hydrate (HOBt•H₂O; 0.20 g, 1.5 mmol) were stirred to dissolve in CH₂Cl₂ (3 mL). The solution was then added with a solution of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC; 0.29 g, 1.5 mmol) in CH₂Cl₂ (5 mL) and stirred for 1 h. The mixture of ethyl 3-aminopropanoate hydrochloride (0.18 g, 1.2 mmol) and triethylamine (0.56 mL, 4.0 mmol) in CH₂Cl₂ (5 mL) was added dropwise into the mixture at 0 °C. The resulting mixture was stirred at room temperature for 3 h. The mixture was evaporated and the crude product was eluted through a silica gel column using hexane and ethyl acetate (1:1 v/v) as the eluent. After the solvent removal, ethyl-3-pentacos-10, 12-diynamidopropanoate (EPCDP) was obtained as a white solid (0.41 g, 87% yield). M.p. (DSC): 72.6 °C; ¹H NMR (400 MHz, CDCl₃) δ 6.03 (s, 1H), 4.16 (q, *J* = 7.0 Hz, 2H), 3.58 – 3.44 (m, 2H), 2.53 (t, *J* = 6.0 Hz, 2H), 2.24 (t, *J* = 7.0 Hz, 4H), 2.14 (t, *J* = 8.0 Hz, 2H), 1.43 – 1.13 (m, 31H), 0.88 (t, *J* = 6.5 Hz, 3H).; ¹³C NMR (101 MHz, CDCl₃) δ 172.6, 172.4, 77.2, 77.0, 64.9, 64.9, 60.3, 36.3, 34.4, 33.7, 31.5, 29.2, 29.0, 28.9, 28.8, 28.7, 28.7, 28.5, 28.4, 28.3, 28.0, 27.9, 25.2, 22.2, 18.8, 18.8, 13.8, 13.7; Anal. Found: C 76.08, H 10.42, N 2.99 (Calcd. for C₃₀H₅₁NO₃: C 76.06, H 10.85, N 2.96).

Ethyl 3-tricos-10,12-diynamidopropanoate (ETCDP): The compound was synthesized and purified according to the above procedure using 10,12-tricosadiynoic acid (0.35 g, 1.0 mmol), β -alanine ethyl ester hydrochloride (0.18 g, 1.2 mmol), HOBt•H₂O (0.20 g, 1.5 mmol), EDC (0.29 g, 1.5 mmol) and triethylamine (0.56 mL, 4.0 mmol). The desired product, ETCDAP, was obtained as a white solid (0.41 g, 91% yield). M.p. (DSC): 63.3°C; ¹H NMR (400 MHz, CDCl₃) δ 6.03 (s, 1H), 4.16 (q, *J* = 7.0 Hz, 2H), 3.64 – 3.33 (m, 2H), 2.53 (t, *J* = 6.0 Hz, 2H), 2.24 (t, *J* = 7.0 Hz, 4H), 2.14 (t, *J* = 8.0 Hz, 2H), 1.51 (s, 4H), 1.42 – 1.09 (m, 27H), 0.88 (t, *J* = 7.0 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 172.6, 172.4, 77.2, 77.0, 64.9, 64.8, 60.3, 36.3, 34.3, 33.7, 31.4, 29.1, 29.0, 28.9, 28.8, 28.7, 28.6, 28.5, 28.4, 28.3, 27.9, 27.9, 25.2, 22.2,

18.8, 18.8, 13.8, 13.7; Anal. Found: C 75.49, H 10.61, N 3.17 (Calcd. for C₂₈H₄₇NO₃: C 75.46, H 10.63, N 3.14).

Ethyl 3-nonadeca-6,8-diynamidopropanoate (ENDDP). The compound was synthesized and purified according to the above procedure using 6,8-nonadecadiynoic acid (0.30 g, 1.1 mmol), β-alanine ethyl ester hydrochloride (0.20 g, 1.3 mmol), HOBt•H₂O (0.22 g, 1.6 mmol), EDC (0.31 g, 1.6 mmol) and triethylamine (0.91 mL, 6.5 mmol). The desired product, ENDDP, was obtained as a white solid (0.42 g, 98% yield); M.p. (DSC): 47.5°C; ¹H NMR (400 MHz, CDCl₃) δ 6.08 (s, 1H), 4.15 (q, *J* = 7.0 Hz, 2H), 3.57 – 3.44 (m, 2H), 2.52 (t, *J* = 6.0 Hz, 2H), 2.33 – 2.07 (m, *J* = 27.0, 14.5, 7.5 Hz, 6H), 1.72 – 1.66 (m, 2H), 1.51 (tt, *J* = 14.5, 7.0 Hz, 4H), 1.29 (dd, *J* = 24.5, 17.0 Hz, 17H), 0.87 (t, *J* = 6.5 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 172.8, 172.6, 77.9, 77.5, 65.9, 65.3, 60.8, 60.5, 36.8, 36.1, 35.0, 34.2, 32.0, 29.6, 29.6, 29.4, 29.2, 28.9, 28.4, 28.0, 24.9, 24.0, 22.8, 19.3, 19.1, 14.3, 14.2; Anal. Found: C 73.45, H 10.23, N 3.70 (Calcd. for C₂₄H₃₉NO₃: C 73.99, H 10.09, N 3.60).

Ethyl 3-octadeca-5,7-diynamidopropanoate (EODDP). The compound was synthesized and purified according to the above procedure using 5,7-heptadecadiynoic acid (0.15 g, 0.54 mmol), β-alanine ethyl ester hydrochloride (0.10 g, 0.65 mmol), HOBt•H₂O (0.11 g, 0.81 mmol), EDC (0.15 g, 0.81 mmol) and triethylamine (0.45 mL, 3.25 mmol). The desired product, EODDP, was obtained as a white solid (0.16 g, 80% yield). M.p. (DSC): 66°C; ¹H NMR (400 MHz, CDCl₃) δ 6.07 (s, 1H), 4.16 (q, *J* = 7.0 Hz, 2H), 3.57 – 3.45 (m, 2H), 2.53 (t, *J* = 6.0 Hz, 2H), 2.36 – 2.20 (m, 6H), 1.91 – 1.75 (m, *J* = 7.0 Hz, 2H), 1.54 – 1.46 (m, *J* = 15.0, 7.0 Hz, 2H), 1.43 – 1.17 (m, *J* = 25.0, 17.5 Hz, 17H), 0.87 (t, *J* = 6.5 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 172.7, 172.1, 78.1, 77.5, 66.4, 65.2, 60.8, 35.2, 35.0, 34.2, 32.0, 29.7, 29.6, 29.4, 29.2, 29.0, 28.4, 24.2, 22.8, 19.3, 18.8, 14.3, 14.2; Anal. Found: C 73.60, H 10.34, N 3.90 (Calcd. for C₂₃H₃₇NO₃: C 73.56, H 9.93, N 3.73).

Ethyl 3-(3-pentacosadiynamidopropanamido) propanoate (EPCDPP). This was synthesized according to the above general procedure from 10, 12-pentacosadiynoic acid (0.64 g, 1.70 mmol), di-β-alanine ethyl ester (0.45 g, 2.38 mmol), HOBt•H₂O (0.34 g, 2.55 mmol), EDC (0.48 g, 2.55 mmol) and triethylamine (1.42 mL, 10.21 mmol), purified by column chromatography with hexane and ethyl acetate (1:1 v/v) as white solid (0.61 g, 66% yield). M.p. (DSC) 121°C; ¹H NMR (400

MHz, CDCl₃) δ 6.31 (s, 1H), 6.19 (s, 1H), 4.16 (q, J = 7.0 Hz, 2H), 3.57 – 3.46 (m, 2H), 2.52 (t, J = 6.0 Hz, 2H), 2.43 – 2.32 (m, 2H), 2.23 (t, J = 7.0 Hz, 4H), 2.14 (t, J = 7.5 Hz, 2H), 1.54 – 1.45 (m, 4H), 1.29 (dd, J = 25.0, 17.5 Hz, 31H), 0.88 (t, J = 7.0 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 173.4, 172.6, 171.8, 77.7, 77.6, 65.4, 65.4, 61.0, 36.9, 35.7, 35.5, 35.0, 34.2, 32.0, 29.8, 29.7, 29.7, 29.6, 29.5, 29.3, 29.3, 29.2, 29.0, 29.0, 28.9, 28.5, 28.4, 25.8, 22.8, 19.3, 19.3, 14.3, 14.2; Anal. Found: C 72.83, H 10.30, N 5.29 (Calcd. for C₃₃H₅₆N₂O₄: C 72.75, H 10.36, N 5.14).

Ethyl 3-(3-tricoso-10, 12-diynamidopropanamido)propanoate (ETCDPP).

This was synthesized according to the above general procedure from 10, 12-tricosadiynoic acid (0.58 g, 1.70 mmol), di- β -alanine ethyl ester (0.67 g, 2.34 mmol), HOBt•H₂O (0.34 g, 2.51 mmol), EDC (0.48 g, 2.51 mmol) and triethylamine (1.40 mL, 10.0 mmol), purified by column chromatography with hexane and ethyl acetate (1:1 v/v) as white solid (0.61 g, 70% yield) M.p. (DSC): 119°C; ¹H NMR (400 MHz, CDCl₃) δ 6.31 (s, 2H), 6.19 (s, 1H), 4.16 (q, J = 7.0 Hz, 3H), 3.68 – 3.37 (m, 6H), 2.52 (t, J = 6.0 Hz, 2H), 2.43 – 2.29 (m, 2H), 2.24 (t, J = 7.0 Hz, 4H), 2.19 – 2.09 (m, 2H), 1.54 – 1.43 (m, 4H), 1.42 – 1.16 (m, 27H), 0.88 (t, J = 7.0 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 172.5, 172.4, 171.7, 78.1, 77.5, 66.3, 65.2, 60.9, 35.7, 35.6, 35.2, 35.1, 34.2, 32.0, 31.6, 29.8, 29.6, 29.6, 29.4, 29.2, 29.0, 28.4, 24.2, 22.8, 19.3, 18.8, 14.3, 14.2; Anal. Found: C, 72.06; H, 10.26; N, 5.44 (Calcd. for C₃₁H₅₂N₂O₄: C, 72.05; H, 10.14; N, 5.42).

Ethyl 3-(3-nonadeca-6,8-diynamidopropanamido)propanoate (ENDDPP).

This was synthesized according to the above general procedure from 6, 8-nonadecadiynoic acid (0.36 g, 1.24 mmol), di- β -alanine ethyl ester (0.50 g, 1.74 mmol), HOBt•H₂O (0.25 g, 1.86 mmol), EDC (0.36 g, 1.86 mmol) and triethylamine (1.0 mL, 7.44 mmol), purified by column chromatography with hexane and ethyl acetate (1:1 v/v) as white solid (0.34 g, 60% yield); M.p. (DSC): 119.8°C; ¹H NMR (400 MHz, CD₃OD) δ 4.14 (q, J = 7.0 Hz, 2H), 3.47 – 3.37 (m, 4H), 2.52 (t, J = 6.5 Hz, 2H), 2.37 (t, J = 7.0 Hz, 2H), 2.31 – 2.13 (m, 6H), 1.75 – 1.60 (m, 2H), 1.57 – 1.44 (m, J = 13.5, 7.0 Hz, 4H), 1.44 – 1.20 (m, 19H), 0.90 (t, J = 6.5 Hz, 3H); ¹³C NMR (101 MHz, CD₃OD) δ 175.9, 173.7, 173.4, 78.1, 77.4, 66.7, 66.3, 61.7, 37.1, 37.0, 36.6, 36.5, 36.4, 36.4, 35.0, 34.4, 33.0, 30.6, 30.6, 30.4, 30.2, 29.9, 29.5, 29.0,

Ethyl 3-(3-octadeca-5, 7-diynamidopropanamido)propanoate(EODDPP).

This was synthesized according to the above general procedure from 5, 7-heptadecadiynoic acid (0.59 g, 2.14 mmol), di- β -alanine ethyl ester (0.86 g, 3.0 mmol), HOBt \cdot H₂O (0.43 g, 3.21 mmol), EDC (0.61 g, 3.21 mmol) and triethylamine (1.78 mL, 12.84 mmol), purified by column chromatography with hexane and ethyl acetate (1:1 v/v) as white solid (0.58 g, 61% yield); M.p. (DSC): 134.4°C; ¹H NMR (400 MHz, CD₃OD) δ 4.15 (q, J = 7.0 Hz, 2H), 3.47 – 3.37 (m, 4H), 2.53 (t, J = 6.5 Hz, 2H), 2.37 (t, J = 6.5 Hz, 2H), 2.33 – 2.16 (m, 6H), 1.85 – 1.71 (m, 2H), 1.59 – 1.01 (m, J = 14.5, 7.5 Hz, 19H), 0.90 (t, J = 7.0 Hz, 3H); ¹³C NMR (101 MHz, CDCl₃) δ 172.5, 172.4, 171.7, 78.1, 77.5, 66.3, 65.2, 60.9, 35.7, 35.6, 35.2, 35.1, 34.2, 32.0, 31.6, 29.8, 29.6, 29.6, 29.4, 29.2, 29.0, 28.4, 24.2, 22.8, 19.3, 18.8, 14.3, 14.2; Anal. Found: C, 69.79; H, 9.67; N, 6.01 (Calcd. for $C_{26}H_{42}N_2O_4$: C, 69.92; H, 9.48; N, 6.27).

2.3 Preparation of paper-based diacetylene indicator and thermal sensing study

A piece of filter paper (Whatman No.1) (1 × 5 cm²) was dipped in diacetylene monomer solution (10 mM) in CH₂Cl₂ and dried in the air for 2 h. Then, it was stored at 4 °C for overnight. Next, the indicators were irradiated by 254 nm UV light for specific periods of time depended on the time required for obtaining the maximum blue phase, typically 10 sec to 2 min. The indicators were attached on the outside of a glass beaker 600 mL filled with 400 mL of water. The beaker was gradually heated from 30 °C to 90 °C while their color images were monitored by webcam and the RGB values were determined from the centered crop area of 15 × 15 pixels by an image-processing program.

2.4 Preparation of paper-based diacetylene indicator and UV sensing study

A piece of filter paper (Whatman No.1) (1 × 5 cm²) was dipped in a solution of diacetylene monomer with designated concentration (10 mM) in CH₂Cl₂ and dried in the air for 2 h. Then, it was stored at 4 °C for overnight. The indicators were irradiated by 254 nm UV light with the UV energy power of 1.4-1.5 mW/cm² for

various periods of time. Their color images of the indicators were recorded by a commercial scanner and the RGB values were determined from the centered crop area of 50×50 pixels by an image-processing program.

2.5 Preparation of paper-based diacetylene indicator and solvent sensing study

A piece of filter paper (Whatman No.1) ($1 \times 5 \text{ cm}^2$) was dipped in a solution of diacetylene monomer with designated concentration (10 mM) in CH_2Cl_2 and dried in the air for 2 h. Then, it was stored at $4 \text{ }^\circ\text{C}$ for overnight. A paper-based indicator was dipped into an organic solvent and surfactant tested at room temperature ($\sim 30 \text{ }^\circ\text{C}$) for 1 min. The indicator pieces were withdrawn from the solvent and allowed to dry in the air. Thirteen organic solvents were tested and deionized water was used for the blank test. The colors of the indicators were recorded by a commercial scanner (Epson Perfection V33) in 3 pieces for each solvent.

2.6 Preparation of paper-based polydiacetylene humidity indicator and humidity sensing study

2.6.1. Single coating of diacetylene carboxylate salts

The single coating of diacetylene carboxylate salts were prepared by using 0.2 M of carbonate salt solution (Na_2CO_3 and K_2CO_3) to dissolve diacetylene monomer (TCDA) and sonicated for 10 minutes to obtain milky solution. The solution was left overnight at room temperature. Then, the solution was dropped on the filter paper and dried at $100 \text{ }^\circ\text{C}$ for 10 minutes. Next, the paper was irradiated by UV light for 1 min.

2.6.2. Layer-by-layer coating of diacetylene carboxylic acid/carbonate salt

The layer-by-layer coating of diacetylene carboxylic acid/carbonate salt was prepared in two methods. In the first method, $20 \text{ }\mu\text{L}$ of 5 mM of TCDA in CH_2Cl_2 was deposited on the filter paper by drop-casting technique and dried in room temperature for 10 minutes. $20 \text{ }\mu\text{L}$ of a saturated carbonate solution (Na_2CO_3 or K_2CO_3) was dropped, dried at $100 \text{ }^\circ\text{C}$ and followed by irradiated with UV light for 1 minute. The second method exploited the opposite deposition sequences, $20 \text{ }\mu\text{L}$ of the

saturated carbonate solution followed by 20 μL of 5 mM of TCDA. After the layer-by-layer deposition, the coated paper was irradiated with UV 254 nm for 1 min.

2.6.3 Zone coating of diacetylene carboxylic acid and carbonate salt

A filter paper strip was divided into 2 zones. The first zone was coated with carbonate salt and the second zone was coated with TCDA monomer. The filter paper strip was dipped into a saturated aqueous solution of the carbonate salt and dried at 100 °C. Then, the other end of the filter paper strip was dipped into a 5mM of TCDA solution in CH_2Cl_2 and the filter paper was dried in a desiccator for 10 minutes. The coated paper was irradiated with 254 nm UV light for 1 minute to generate a humidity indicator with blue PDA zone on one end and off-white zone of the carbonate salt on the other end. The dipping process was performed with care to make sure that these two zones are separated by 3 mm.

CHAPTER III

RESULTS AND DISCUSSION

This dissertation involved the study of diacetylene compounds with three types of functional groups including carboxylic acid, amide and diamide. Each series of the diacetylenes have four members with different number of methylene chains (Scheme 3.1). The results of the synthesis and utilization of these diacetylene compounds as sensing materials are reported and discussed in this chapter which is divided into 5 sections *i.e.* synthesis, UV indicators, thermochromic study, solvatochromic study and humidity indicators.

3.1 Synthesis of diacetylene monomers

The synthesis of the diacetylene monomers containing β -alanine ethyl ester and di- β -alanine ethyl ester were accomplished by condensing the commercially available diacetylene fatty acids (PCDA, TCDA, NDDA, ODDA) with β -alanine ethyl ester and di- β -alanine ethyl ester by using EDC and HOBT as coupling agents (Scheme 3.1, see section 2.2 for detail synthetic procedures). The monoamides (EPCDP, ETCDP, ENDDP, EODDP) were obtained in excellent yields (80-98%) and the diamides (EPCDPP, ETCDPP, ENDDPP, EODDPP) were also obtained in satisfactory yields (60-70%).

Scheme 3.1 Synthesis of diacetylenes containing amide and diamide head groups.

The ^1H NMR spectra of the diacetylene compounds comprising β -alanine ethyl ester in CDCl_3 were shown in Figure 3.1. These monomers have a characteristic quartet peak ~ 4.2 ppm corresponding to OCH_2 (d') in the ethyl ester and triplet peak ~ 3.5 ppm belonging to NCH_2 in the amido group (b'). The signals of amido proton appeared as a singlet peak (a') near 6.1 ppm and those of methylene proton c' appeared as triplet peak near 2.5 ppm. The chemical shift of the methylene protons between the amide and the diacetylene group were observed in the range of 1.4-2.5 ppm.

Figure 3.1 ^1H NMR spectra of mono- β -alanine ethyl ester diacetylene monomers a) EPCDP, b) ETCDP, c) ENDDP, d) EODDP in CDCl_3 .

The ^1H NMR spectra of the diacetylene monomers containing di- β -alanine ethyl ester (Figure 3.2) have a characteristic quartet peak (g') around 4.2 ppm and multiplet peak around 3.5 ppm corresponding to the methylene groups b' and e' . The signals near 6.2 and 6.4 ppm, corresponding to the amido N-H protons (a' and d'), and the signals in the range of 1.4-2.6 ppm matched the methylene proton between the amide and the diacetylene group.

Figure 3.2 ^1H NMR spectra of dipropanamide diacetylene monomers a) EPCDPP in CDCl_3 , b) ETCDDPP in CDCl_3 , c) ENDDPP in CD_3OD , d) EODDDPP in CDCl_3

3.2 UV indicators

The UV sensing indicators were prepared from all 12 diacetylene monomers having 3 different head groups including carboxylic acid (PCDA, TCDA, NDDA, ODDA), β -alanine ethyl ester (EPCDDP, ETCDDP, ENDDDP, EODDDP), di- β -alanine ethyl ester (EPCDPP, ETCDDPP, ENDDPPP, ODDPPP). Typically, the indicator was prepared by dipping a strip of filter paper ($1 \times 5 \text{ cm}^2$) in a CH_2Cl_2 solution of the diacetylene monomer (10 mM) followed by air dry and stored in a refrigerator before further sensing study.

3.2.1 UV sensing study

The white diacetylene coated paper strips were irradiated by 254 nm UV light with the intensity of $1.4\text{-}1.5 \text{ mW/cm}^2$ for various periods of time. The paper strips were periodically removed from the irradiation area and the color images were recorded by a commercial scanner. Each image of the indicator was taken from

individual sample. As shown in Figure 3.3, the color of all PDAs on the paper rapidly changed their color from white to blue or purple within 10 seconds. With prolong irradiation, the blue or purple PDAs gradually turned into red or orange color at different irradiation time depending on the structures of the diacetylene monomers. From the color images, the diacetylenes in the series of the same head group with shorter alkyl chain, either between the diyne and carboxyl group or in the lipid tail (lower n or m numbers), required shorter irradiation time to cause the blue-to-red color transition indicating their greater UV sensitivity. Furthermore, the diacetylene compounds with amide and diamide head groups are generally more sensitive than those with carboxylic acid head group.

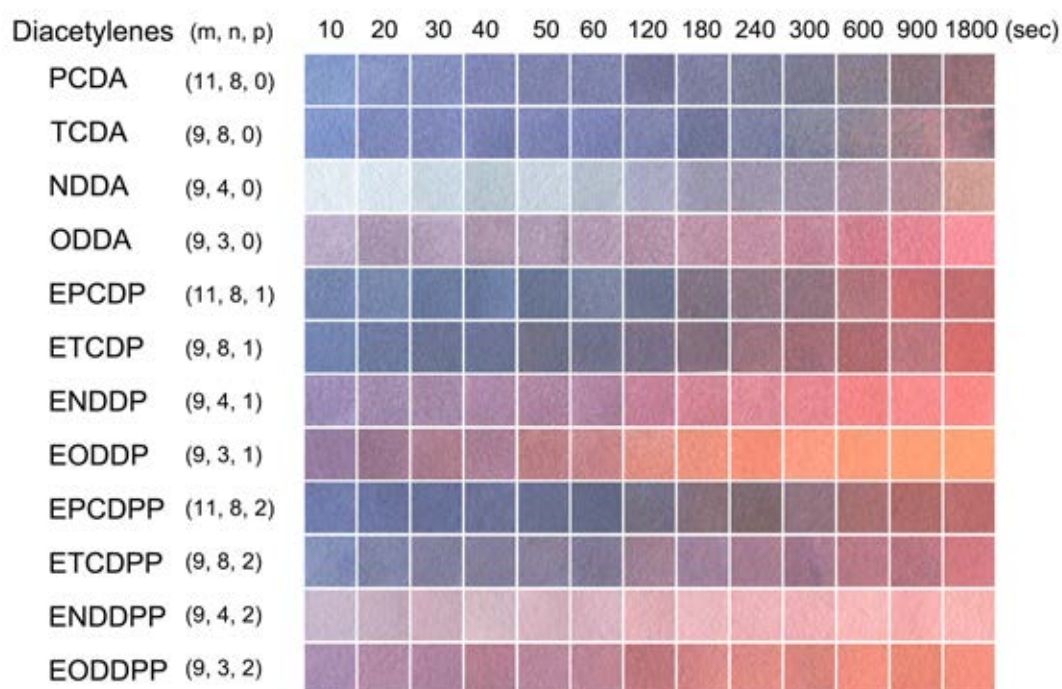

Figure 3.3 Color images of PDA indicators obtained at different UV irradiation times.

3.2.2 Determination of UV doses required for blue-to-red color transition

For the determination of the color transition of the paper-based polydiacetylene indicators, the color transition images of the indicators (Figure 3.3)

were converted to RGB values by image-processing program. The R, G and B values represent the extent of the red, green and blue components in the image. The values are varied from 0 to 255 that the greater the value is the higher the extent of the hue. For examples, the RGB coordinate of (0, 0, 0) is white and (255, 255, 255) is black.

For better comparison of the colorimetric responses, the effects from the background light and color depth were evened out by using the percentage value of each RGB component calculated according to the following equation shown below, instead of its absolute value.

$$\%R(\text{or } \%G \text{ or } \%B) = (R(\text{or } G \text{ or } B))/(R+G+B) \times 100$$

To obtain the UV dose (mJ/cm^2), the irradiation time (s) was multiplied by with the intensity (mW/cm^2) of the UV light. The plot of %R and %B against the UV dose clearly showed the increase of %R in the expense of %B while %G remained relatively constant (Figure 3.4). The small error bars in the plots confirmed high reproducibility of the indicator preparation and color measurement.

Figure 3.4 Plots of %R (▲), %G (◆) and %B (●) against UV doses of PDA indicators prepared from PCDA. Error bars represent standard deviations.

To apply the RGB values for the sensitivity evaluation, the UV dose required at the intersection between %R and %B curves was assigned as the color transition dose. As shown in Figure 3.5, the UV doses required for the blue-to-red color

transition of all diacetylene monomers can be easily determined from the crossing point. By visual observation, these color transition points correspond to purple color.

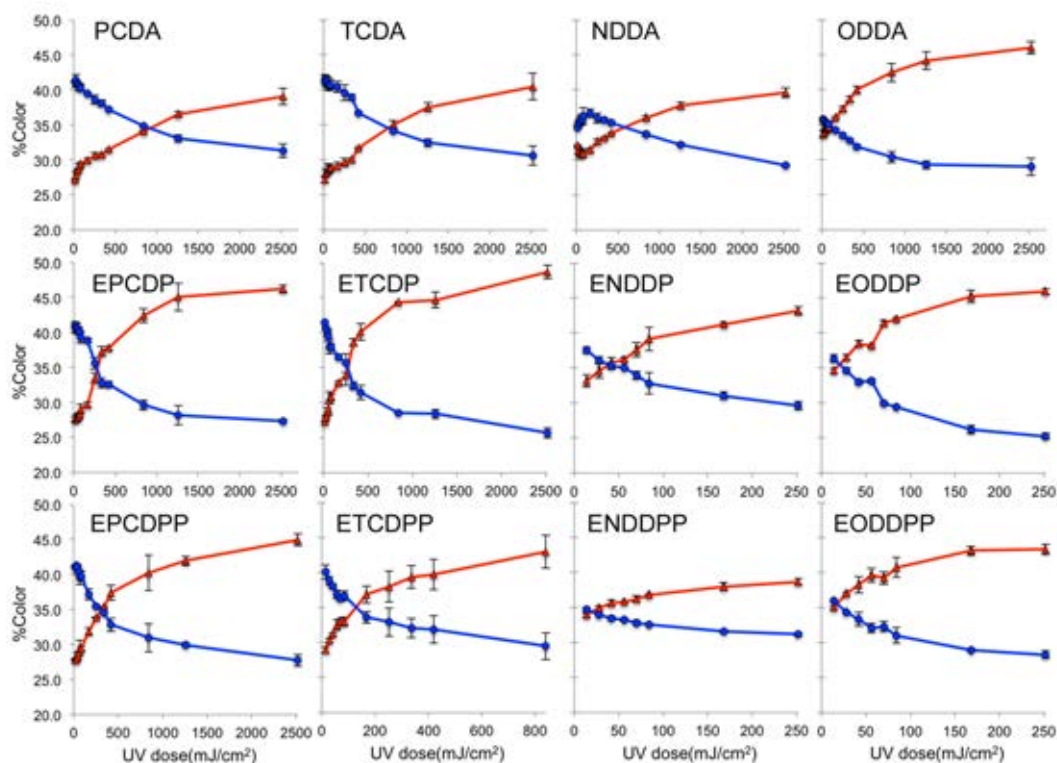

Figure 3.5 Plots of %R (▲) and %B (●) of the PDA indicators against UV irradiation doses. Error bars represent standard deviations.

The blue-to-red color transition doses determined from the intersection point of %R and %B are compiled in Table 3.1. The diacetylene that gives the lower dose required for the color transition is more UV sensitive. For examples, TCDA, ETCDP and ETCDPP required the exposure doses of 780 ± 52 mJ/cm², 264 ± 32 mJ/cm² and 130 ± 9 mJ/cm², respectively, that represent the sensitivity order of TCDA < ETCDP < ETCDPP.

Table 3.1 UV doses required for blue-to-red color transition of the indicators prepared from various diacetylene compounds

Compound	UV dose (mJ/cm ²)	Compound	UV dose (mJ/cm ²)	Compound	UV dose (mJ/cm ²)
PCDA	918±19	EPCDP	276±17	EPCDPP	309±3
TCDA	780±52	ETCDP	264±32	ETCDPP	130±9
NDDA	586±24	ENDDP	39±11	ENDDPP	20±4
ODDA	98±22	EODDP	21±1	EODDPP	18±1

To realize the structure-activity relationships of the diacetylene compounds with their UV induced color transition, the data in Table 3.1 were plotted into a bar chart as shown in Figure 3.6. From the chart, there is a clear trend of the UV doses required for the color transition within the series of the same head group. The diacetylenes with shorter alkyl chain (lower n or m numbers), either between the diyne and carboxyl group or in the lipid tail, required lower UV doses in causing the blue-to-red color transition indicating their greater UV sensitivity. This result suggested a photo-induced thermochromism, which will be described in more details in section 3.3.

Comparing between the series of different head groups, the UV doses required for the color transition of the fatty acid series (PCDA, TCDA, NDDA and ODDA) are generally greater than those of the corresponding monopropanamide (EPCDP, ETCDP, ENDDP and EODDP) and dipropanamide (EODDPP, ENDDPP, ETCDPP and EPCDPP). The effects of the head group on the UV sensitivity are likely associated with the difference of orientation and strength of hydrogen bonding among the carboxylic acid and amido head groups in the molar self-assemblies of the diacetylene lipids. Since the blue-to-red transition of the amide series is faster in the UV irradiation, their molecular assemblies are probably more readily to undergo the conformational alteration during the topopolymerization process. Further details on the roles of the head groups on the color transition sensitivity will be discussed in the section 3.3 related to the thermochromism properties.

Figure 3.6 Bar chart of UV doses required for causing blue-to-red color transition of diacetylene-based paper sensors. The plots are the average data obtained from 3 independent samples with the error bars representing the standard deviation.

3.3.3 Morphology change of PDA upon UV irradiation

Scanning electron microscopy (SEM) of the blue and red PDA coated on cellulose fibers of the filter paper strips revealed interesting microscopic phenomena. The diacetylene containing carboxylic acid head group showed PDA film rupture upon the UV induced color transition from blue to red (Figure 3.7 a and d). However, no significant change was observed for the PDAs obtained from the diacetylene containing mono- and diamide head groups. The rupture denoted that the blue-to-red color transition was accompanied with a major and sudden change in the molecular assembly [54].

Figure 3.7 SEM (5 kV) micrographs of filter paper coated with blue PDAs (a) PCDA (b) EPCDP (c) EPCDPP and red PDAs of (d) PCDA (e) EPCDP (f) EPCDPP. The scale bars represent 5 μm .

3.3 Thermochromic study

Scheme 3.2 Steps in preparation and thermal sensing study of paper-based PDA indicators: a) dip-coating, b) drying, c) UV irradiating, d) visualizing after UV irradiation, e) apparatus set-up for thermal sensing study before heating, f) indicators after heating, g) color images of indicators at various temperature and h) data processing for determination of color transition temperature.

3.3.1 Preparation of paper-based diacetylene indicator for thermal sensing study

For thermal sensing study, the indicators were prepared by a dip coating of filter paper with a diacetylene monomer followed by UV irradiation according to the scheme 3.2. Typically, a strip of filter paper was dipped into a solution of the diacetylene monomer in CH_2Cl_2 . The dry paper strip was irradiated with 254 nm UV

light at room temperature to generate a blue paper-based PDA indicator (Table 3.2). The formation of blue color indicated a successful polymerization of the diacetylene monomer to its corresponding PDA. The irradiation period for each monomer was varied depending on their UV sensitivity that has been described earlier in section 3.2. After the photopolymerization process, the indicator was ready to be used in thermal sensing study.

Table 3.2 Irradiation time and color appearance of paper-based PDA indicators

Diacetylenes	Irradiation time	Color	Diacetylenes	Irradiation time	Color	Diacetylenes	Irradiation time	Color
PCDA	60		EPCDP	30		EPCDPP	10	
TCDA	60		ETCDP	20		ETCDPP	10	
NDDA	180		ENDDP	10		ENDDPP	10	
ODDA	10		EODDP	10		EODDPP	10	

3.3.2 Color transition of PDA indicator by temperature

The paper indicators were adhered to the side of the beaker 600 mL and they were heated from 30 °C to 90 °C. The color images (Figure 3.9) of the indicators were recorded by a commercial webcam.

*m and n are the numbers of methylene groups while p is the the number of β -alanine units in the diacetylene monomers (see Scheme 3.1)

Figure 3.8 Color images of PDA indicators captured at different temperatures.

As shown in Figure 3.8, the color transition temperatures of the PDAs from the diacetylenes within the series of the same head group decrease with decreasing methylene chain length (n or m numbers) showing the higher thermal sensitivity that is in the same trend with the UV sensitivity of the diacetylenes. Furthermore, the PDAs with amide and diamide functional groups generally changed their color from blue to red at lower temperature than those with the same number of methylene groups but consisting of carboxylic acid functional group.

3.3.3 Determination of color transition temperatures

Using the RGB values according to the procedures described in section 3.2.3, the color transition temperatures were successfully determined from the color images of the indicators (similar to Figure 3.8). The plots of %R and %B against the

temperature gave the crossing point, assigned as the color transition temperatures (Figure 3.9).

Figure 3.9 Plots of %R (▲) and %B (●) of the PDA indicators against temperature. Error bars represent standard deviations.

The color transition temperatures determined from the crossing point of %R and %B are listed in Table 3.3. The diacetylene that gives the lower temperature is more thermal sensitive. For examples, TCDA, ETCDP and ETCDPP changed their color from blue to red at 62.3 ± 0.6 °C, 56.4 ± 0.7 °C and 55.6 ± 0.8 °C, respectively. The trends of the color transition temperatures determined from the RGB values are in good agreement with the trends of the color changes observed by naked eyes described in section 3.3.1.

Table 3.3 Color transition temperatures of the PDA indicators prepared from various diacetylene compounds

Compound	T (°C)	Compound	T (°C)	Compound	T (°C)
PCDA	69.7±0.9	EPCDP	63.1±0.6	EPCDPP	65.7±1.0
TCDA	62.3±0.6	ETCDP	56.4±0.7	ETCDPP	55.6±0.8
NDDA	49.6±1.2	ENDDP	34.5±0.9	ENDDPP	36.7±1.6
ODDA	<30	EODDP	<30	EODDPP	<30

The color transition temperatures of the PDAs were plotted as the red dots in Figure 3.10. The plot clearly shows the increase of temperature sensitivity with the decrease of the aliphatic chain length. In thermochromism, the role of the alkyl side chains on the temperature sensitivity has been attributed to the increase of their hydrophobic interaction, which in turn stabilizes the π -conjugated backbone [5,9,37]. The plot also shows that the color transition temperatures of the carboxylic acid series (PCDA, TCDA, NDDA and ODDA) are generally higher than those of the corresponding monoamide (EPCDP, ETCDP, ENDDP and EODDP) and diamide (EODDPP, ENDDPP, ETCDPP and EPCDPP). These quantitative results are well correlated with the color changes observed by eyes (Figure 3.8). The effects of the head group on the thermal sensitivity are related to the strength of hydrogen bonding among the polar head groups in the molecular self-assemblies of the diacetylene lipids[2,44]. The higher color transition temperatures of the carboxylic acid series thus suggest that the hydrogen bonding of the carboxylic head groups is stronger than that of the amide head groups.

Figure 3.10 Color transition temperatures (●) and UV-doses (■) of diacetylene-based paper sensors. The plots are the average data obtained from 3 independent samples with the error bars representing the standard deviation.

To gain insight mechanism of the blue-to-red color transition induced by the UV irradiation, the color transition UV-doses (purple bars) of the PDAs were plotted in the same chart (Figure 3.10) with the color transition temperatures. Within each series, the chart shows the same trend of the color transition temperature and color transition UV-doses. This similarity suggests that the photo-induced thermochromism [42] is responsible for the sensitivity trend of the PDAs with the same side chain head groups observed during the UV irradiation. However, the comparison of thermal sensitivity between the series is not well correlated with their UV sensitivity. For example, the blue-to-red transition of EPCDP, a monopropamide derivative, was observed at a much lower UV dose comparing with TCDA while both of them showed very similar color transition temperature. This difference is even more pronounced when comparing EPCDPP, a dipropamide derivative, with TCDA; the less thermally sensitive EPCDPP is significantly more UV sensitive than TCDA. The results demonstrated that the color transition caused by UV irradiation is not solely driven by the photo-induced thermochromism. The blue-to-red transition during the UV irradiation of some PDAs has also been attributed to the conformational change caused by the propagation of the polymer chain [44,55,56]

3.3.4 Morphology change of PDAs upon heating

For SEM micrographs, the morphologies of polydiacetylene thermal indicators are shown in Figure 3.11. The red phase of diacetylene containing carboxylic acid head group showed PDA film rupture (Figure 3.11d) after being heated to 90 °C similar to that observed in the photo process (Figure 3.7d). Moreover, there are no morphology changes observed upon the thermochromic transition of PDAs with mono- and diamide groups (Figure 3.11 e and f).

Figure 3.11 SEM (15 kV) micrographs of the filter paper coated with PDAs before heating: (a) PCDA (b) EPCDP (c) EPCDPP, and after heating: (d) PCDA (red) (e) EPCDP (red) (f) EPCDPP (purple).

3.4 Solvent sensing study

As PDAs are known to have solvatochromism, a color change upon a solvent contact, the PDAs from 6 monomers i.e. TCDA, PCDA, ETCDP, EPCDP, ETCDDP and EPCDDP were investigated for fabrication of an indicator array for solvent detection and identification. The indicators were prepared on filter paper by dip-coating technique from the diacetylene monomer solutions. The diacetylene coated paper strips were irradiated with 254 nm UV light to obtain the blue PDA indicators. To test the solvent sensing properties, the indicators were soaked with 14 solvents for 1 minute and allowed to dry in the air for 10 minutes. The color images of the indicators before and after solvent testing were recorded by a commercial scanner to determine the extent of their colorimetric responses.

As shown in Figure 3.12, the 6 PDA indicators show an array of colorimetric responses upon the contact with various solvents. The RGB values of the color images were evaluated by image processing software to provide a set of 756 RGB numerical data (3 RGB values \times 14 solvents \times 6 indicators \times 3 replicates) as tabulated in Table D1-D6. These data were analyzed by principal component analysis (PCA) to generate clusters of PCA scores as shown in Figure 3.13. The PC score plot showed that the first and second components (PC1, PC2, PC3) accounted for 98.68%, 0.75% and 0.27% of the data variance, respectively. To evaluate the classification accuracy, linear discriminant analysis (LDA) was applied on the PC scores to cross validate the discriminating ability using a leave-one-out technique. The LDA cross validation gave 74% classification accuracy indicating relatively low discriminating ability of this indicator array for the 14 solvents. With careful inspection of the cross validation results, the problematic solvents, which cannot be discriminated, are ethylacetate, acetone and toluene.

Figure 3.12 Color images of PDA indicators obtained after exposure to different solvents.

Figure 3.13 PCA score plots of the RGB values obtained from water (control) and 13 organic solvents tested by a sensing array PDA indicators.

3.5 Humidity indicators

The designs of paper-based PDA humidity indicators are based on the alkalinochromism of acidic PDAs using carbonate salts as the source of alkalinity. Two carbonate salts, Na_2CO_3 and K_2CO_3 were tested with two acidic diacetylene monomers, PCDA and TCDA. Three methods for the monomer and carbonate salt deposition on filter paper (Whatman No. 3), i.e. 1) single coating of diacetylene

carboxylate salts, 2) layer-by-layer coating of diacetylene carboxylic acid/carbonate salt and 3) zone coating of diacetylene carboxylic acid and carbonate salt, were investigated.

3.5.1 Single coating of diacetylene carboxylate salts

The diacetylene carboxylate salt was prepared by sonication of TCDA in a carbonate salt solution (Na_2CO_3 or K_2CO_3) until a milky solution was formed. The solution was left overnight at room temperature. The solution was then dropped on the filter paper, dried and irradiated by UV light. The paper coated with TCDA-Na^+ turned into sporadic black spots (Figure 3.14) while those of TCDA-K^+ indicators showed uneven purple spots. After exposed to the ambient humidity, the TCDA-Na^+ indicator did not show any apparent change while the color of TCDA-K^+ indicator changed from purple to red. It seems that the TCDA-K^+ salt may be useful as a moisture sensitive material, however this single coating of diacetylene carboxylate salt did not give uniform color on the filter paper. Better fabrication technique is needed.

Figure 3.14 Images of indicators prepared from a single coating of TCDA carboxylate salts before and after exposed to the ambient humidity for 24 h.

3.5.2 Layer-by-layer coating of diacetylene carboxylic acid/carbonate salt

The layer-by-layer coating of diacetylene carboxylic acid/carbonate salt was performed in two ways. In the first method, TCDA was deposited on the filter paper

first and followed by the deposition of carbonate salt (Na_2CO_3 or K_2CO_3). The second method utilized the opposite deposition sequences, the carbonate salt followed by TCDA. After the layer-by-layer deposition, the coated paper was irradiated with UV 254 nm for 1 min. In the first method, TCDA with Na_2CO_3 did not polymerize (Figure 3.15) while that with K_2CO_3 polymerized to give a purple spot. After the exposure to the ambient humidity, there was no change for the indicators with Na_2CO_3 but the indicators with K_2CO_3 became more reddish. In the second method, TCDA with Na_2CO_3 gave a red spot while that with K_2CO_3 gave a purple spot after the UV irradiation. The indicator with Na_2CO_3 did not change its color while that with K_2CO_3 became more reddish after the exposure to the ambient humidity. All the results suggest that the K_2CO_3 salt is more appropriate for preparation of humidity indicators. However, the color transition from purple to reddish-purple was not satisfactory to indicate the change of humidity. Therefore, another fabrication method was attempted as described in the next section.

Figure 3.15 Images of indicators prepared by layer-by-layer coating of TCDA and carbonate salt before and after exposed to the ambient humidity for 24 h.

3.5.3 Zone coating of diacetylene carboxylic acid and carbonate salt

In this final preparation method, a filter paper strip was divided into 2 zones. The first zone was coated with carbonate salt and the second zone was coated with TCDA monomer. The filter paper strip was dipped into a saturated aqueous solution of the carbonate salt and dried at 100 °C. Then, the other end of the filter paper strip was dipped into a TCDA solution in CH_2Cl_2 and the filter paper was dried in a desiccator. The coated paper was irradiated with 254 nm UV light to generate a

humidity indicator with blue PDA zone on one end and off-white zone of the carbonate salt on the other end. The dipping process was performed with care to make sure that these two zones are separated by 3 mm (See Scheme 3.3 for the preparation steps).

To test the humidity sensitivity, the indicator samples were placed in the chamber of which relative humidity (%RH) was controlled by a saturated NaBr solution. The color images of the indicators were recorded by a webcam (1.4 Mpixel). The %RH within the chamber was monitored with a hygrometer which showed relatively constant humidity of 62 ± 1 %RH throughout the entire experimental period of 24 h. The color image of the blue zone was cropped and processed to obtain the RGB values for further analysis of the color transition time.

Scheme 3.3 Steps in preparation and humidity indicators from TCDA and carbonate salt using zone coating technique: a) dry filter paper strip coated with saturated carbonate solution, b) dip-coating of TCDA solution, c) UV irradiation of the TCDA zone, d) blue PDA zone appearance after UV irradiation, e) apparatus set-up for humidity sensing study, f) color change of the indicators captured by a webcam.

In Figure 3.16, the blue TCDA zone fabricated next to Na_2CO_3 did not change its color within 24 hours of the humidity exposure. On the other hand, the blue TCDA zone with K_2CO_3 started to turn red from the edge near the carbonate zone after 3 hours and the red color gradually expanded to fill the entire TCDA zone within 24 h.

An intersection point was observed in the plot of %R and %B against the exposure time for the indicator coated with K_2CO_3 around 6 h but not for the indicator using Na_2CO_3 salt (Figure 3.17). This allows the determination of the color transition time at specific relative humidity. The different colorimetric responses of the PDA to the different carbonate salts may be rationalized by the fact that Na_2CO_3 is less hygroscopic than K_2CO_3 [57] or the indicators fabricated with K_2CO_3 , the filter paper became dampen after the humidity test while those fabricated with Na_2CO_3 remained relatively dry. Furthermore, the blue TCDA zone fabricated next to K_2CO_3 in 75% RH changed their color from blue to red within 3 h while those in 42% RH did not change their color (Figure 3.18). The crossing point of the plot of %R and %B against the exposure time in 75% RH for the indicator coated with K_2CO_3 was around 6 h but not for the indicator in 42% (Figure 3.19). Comparing the different PDA, the PCDA indicator with K_2CO_3 can change their color from blue to red in 62% RH and the plots of %R and %B against time showed that the indicator prepared from PCDA had similar humidity sensitivity as that from TCDA (Figure 3.20). After K_2CO_3 absorbs moisture in the air, the base gradually diffused toward the less concentrated area and attracted more moisture to the dry interface. By this mechanism and the alkalinochromism effect, the blue color of the PDA turned into red color with good time dependence. This time dependent colorimetric transition is highly desirable to indicate when the moisture-protected products have unintentionally exposed to the ambient humidity for an unacceptable period.

Figure 3.16 Color images of TCDA zone of the humidity indicators prepared with (a) Na_2CO_3 and (b) K_2CO_3 captured at different exposure times in a closed chamber having $62\pm 1\%$ RH.

CHAPTER IV

CONCLUSION

In conclusion, a novel series of diacetylene lipid monomers containing mono- and di- β -alanine ethyl ester with various length of methylene spacers were successfully synthesized. The diacetylene lipids were fabricated onto filter paper and photopolymerized by 254 nm UV light. The indicators were studied for 4 types of applications i.e. UV-dose indicators, temperature indicators, solvent indicators and humidity indicators. The color transitions of the indicators were determined from their color images using the RGB color system in which the crossing point of %B and %R curves from their plots against the independent variables such as time and temperature.

In UV sensing study, the coarse tuning of the UV sensitivity was achieved by converting the lipid head group from carboxylic acid to the amide or diamide, which ably affects the photochromism sensitivity, while the fine tuning was possible by varying the aliphatic chain length, which progressively affects the photo-induced thermochromism sensitivity. The conversions of the head groups from the carboxylic acid to the amide groups alter the intermolecular interaction and orientation in the monomer assembly.

In the thermal sensing study, the color transition temperature of the indicator increased with the aliphatic chain length. The carboxylic acid series (PCDA, TCDA, NDDA and ODDA) generally gave higher color transition temperature than those of the corresponding monoamide (EPCDP, ETCDP, ENDDP and EODDP) and diamide (EODDPP, ENDDPP, ETCDDP and EPCDDP). Comparing between different functional groups, thermal sensitivity was not always in line with UV sensitivity that demonstrated other mechanisms beyond the photo-induced thermochromism for the blue-to-red color transition induced by UV light.

In the solvent sensing study, 6 PDAs were used in the construction of the indicator array for detecting and identifying 14 solvents. The colorimetric responses were evaluated using RGB color system and analyzed by principal component

analysis (PCA). The 756 RGB numerical values (3 RGB values \times 14 solvents \times 6 indicators \times 3 replicates) were transformed into clusters of PCA scores corresponding to each solvent. However, the LDA cross validation gave only 74% accuracy indicating relatively low discriminating ability of this array for classification of all 14 solvents.

In humidity sensing study, the humidity indicator was successfully fabricated by zone coating of TCDA and K_2CO_3 . The edge of blue PDA zone next to the K_2CO_3 zone started to turn red after 3 hours and the red color gradually expanded to fill the entire PDA zone within 24 h at 62% RH. The indicator exhibited faster color transition at 75% RH where the entire PDA zone turned the color from blue to red within 3 h while the indicator became essentially insensitive at 42% RH. The plots of %R and %B against time showed that the indicator prepared from PCDA had similar humidity sensitivity as that from TCDA. The humidity sensitivity is governed by the alkalinochromism effect that depends on the rate of moisture absorption and diffusion on the filter paper coated with the carbonate salt. This time dependent colorimetric transition is highly desirable to indicate when the moisture-protected products have unintentionally exposed to the ambient humidity for an unacceptable period.

The monomer structures, sensor preparation and evaluation techniques devised in this dissertation should serve as guidelines for systematic study of PDA paper-based indicators toward the development of economical and reliable colorimetric sensors for various applications.

Abstract

A series of paper-based polydiacetylene UV sensors containing with β -alanine ethyl ester and di- β -alanine ethyl ester were fabricated and investigated by photo scanner and analyzed by an image processing software. The tuning of the UV sensitivity was achieved by converting the lipid head group from carboxylic acid to the amide or diamide.

KEYWORDS: Polydiacetylene, UV Sensor, RGB

1. Introduction

Ultraviolet radiation is a very useful electromagnetic wave, which is commonly applied in germicidal and chemical curing processes of many products such as foods,

medicines, polymers and printing materials. On the other hand, excessive UV exposure is very harmful to human health, animals and plant life. For useful applications and hazardous precaution, the amount of radiation or so-called UV dose should be monitored and controlled. Therefore, development of a tool which can detect and record UV doses in real time is of importance. Currently, available techniques used in UV dose determination include photoelectric measurement [1] and colorimetric methods. The colorimetric method offers an attractive feature in the possibility for instrumentless naked eye detection or warning labels. Classes of compounds commonly used in colorimetric display of UV doses are spiropyran or spirooxazine [2]. This type of compounds change from colorless to darker color upon exposure to UV radiation that is not easily judged for the critical UV dose [3]. Furthermore, tunable sensitivity of the sensing materials is highly desirable but it has not been well established for such compounds.

Diacetylenes are a promising class of colorimetric UV responsive compounds due to their distinct color change with tunable sensitivity [4]. Color transitions of polydiacetylenes (PDAs) by heat [5], solvent [6], mechanical stress [7], molecular recognition [8], and pH [9] have been extensively investigated and PDAs have been applied as sensing materials in various form [10]. Self-assembled amphiphilic diacetylene lipids are readily polymerized to form conjugated PDAs with intense color. Although the color change of PDAs from blue to red by prolong UV irradiation have been noted, their color transition mechanism remains a topic under debate [11] and their applications for UV dose sensors have not been directed. Here, we would like to report our study on two series of diacetylene amido lipids (Figure 1) containing mono- and diamide head groups with variable lengths of methylene spacers in comparison with their diacetylene fatty acid analogue aiming for tunable colorimetric UV responsive materials.

2. Experimental

2.1 Materials and equipment

10,12-Pentacosadiynoic acid (PCDA), 10,12-tricosadiynoic acid (TCDA), 6,8-nonadecadiynoic acid (NDDA) and 5,7-octadecadiynoic acid (ODDA) were purchased from GFS Chemicals USA, and other reagents were purchased from Sigma-Aldrich and Fluka. Analytical grade solvents were used without further purification. For extraction and chromatography, solvents were commercial grade and they were distilled prior to use. Column chromatography was performed on Merck silica gel 60 (70-230 mesh). Thin layer chromatography (TLC) was carried out using Merck 60 F254 plates with a thickness of 0.25 mm. All diacetylene monomers were dissolved in chloroform and filtered before use, to remove the unintentionally polymerized monomers. The ^1H and ^{13}C NMR spectra were collected on a 400 MHz NMR spectrometer (Mercury 400, Varian). The color transitions of PDAs were monitored and recorded by a scanner (Epson Perfection V33) for UV sensing or a webcam (ICON228, 14M pixels) linked to a commercial laptop computer.

2.2 Synthesis of diacetylene monomers

2.2.1 Ethyl 3-(pentacos-10,12-diynoylamido)propanoate (EPCDP)

10,12-Pentacosadiynoic acid (0.38g, 1.0 mmol) and 1-hydroxybenzotriazole hydrate (HOBt•H₂O; 0.20 g, 1.5 mmol) were stirred to dissolve in CH₂Cl₂ (3 mL). The solution was then added with a solution of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC; 0.29 g, 1.5 mmol) in CH₂Cl₂ (5 mL) and stirred for 1 h. The mixture of ethyl 3-aminopropanoate hydrochloride (0.18 g, 1.2 mmol) and triethylamine (0.56 mL, 4.0 mmol) in CH₂Cl₂ (5 mL) was added dropwise into the mixture at 0 °C. The resulting mixture was stirred at room temperature for 3 h. The mixture was evaporated and the crude product was eluted through a silica gel column using hexane and ethyl acetate (1:1 v/v) as the eluent. After the solvent removal, ethyl-3-pentacos-10,12-diynamidopropanoate (EPCDP) was obtained as a white solid (0.41 g, 87% yield).

2.3 Preparation of paper-based diacetylene indicator and UV sensing study

A piece of filter paper (Whatman No.1) ($1 \times 5 \text{ cm}^2$) was dipped in a solution of diacetylene monomer with designated concentration (10 mM) in CH_2Cl_2 and dried in the air for 2 h. Then, it was stored at $4 \text{ }^\circ\text{C}$ for overnight. The indicators were irradiated by 254 nm UV light with the UV energy power of $1.4\text{-}1.5 \text{ mW/cm}^2$ for various periods of time. Their color images of the indicators were recorded by a commercial scanner and the RGB values were determined from the centered crop area of 50×50 pixels by an image-processing program.

2.4 Preparation of paper-based diacetylene indicator and thermal sensing study

A piece of filter paper (Whatman No.1) ($1 \times 5 \text{ cm}^2$) was dipped in a diacetylene monomer solution (10 mM) in CH_2Cl_2 and dried in the air for 2 h. Then, the indicators were irradiated by 254 nm UV light for specific periods of time depended on the time required for obtaining the maximum blue phase, typically 10 sec to 2 min. The indicators were attached on the outside of a glass beaker 600 mL filled with 400 mL of water. The beaker was gradually heated from $30 \text{ }^\circ\text{C}$ to $90 \text{ }^\circ\text{C}$ while their color images were monitored by webcam and the RGB values were determined from the centered crop area of 15×15 pixels by an image-processing program.

Results and discussion

The diacetylene fatty acids i.e. ODDA, NDDA, TCDA and PCDA (Figure 1) were commercially available. The ethyl-3-amidopropanoate derivatives (EODDP, ENDDP, ETCDP and EPCDP) and the corresponding diamides (EODDPP, ENDDPP, ETC DPP and EPCDPP) of the diacetylene fatty acids were synthesized from the carboxyl/amino condensation between the fatty acids and the mono- and di- β -alanine ethyl esters using 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) and hydroxybenzotriazole hydrate (HOBt) as the coupling reagents (Scheme S1). For portable and disposable applications,

paper is a very practical substrate for preparation of colorimetric sensors as it is omnipresent in white color, inexpensive and easy to be stored, transported and handled [12]. We have successfully fabricated PDA paper-based sensors by simple dipping filter paper (Whatman No.1) into the diacetylene monomer solutions (10 mM) followed by UV irradiation [13]. In this work, after an air dry, the monomer coated paper strips were stored at 4 °C for at least 12 h before their UV sensing properties were studied at 26.5 ± 1.5 °C by irradiation with a 254 nm UV lamp at a power intensity of 1.40 ± 0.05 mW/cm². At designated time intervals, the paper strips were removed from the irradiation zone and their colors were recorded by a photo scanner (300 dpi). The white diacetylenes coated paper initially turned blue or purple within ten seconds of the irradiation (Figure 2) signifying efficient topopolymerization of the diacetylene monomers to form the corresponding blue phase PDAs [14]. Extending the UV exposure time, the blue color changed to red at different irradiation time depending on the diacetylene structures. It is important to mention here that UV-vis absorption spectroscopy is not applicable for paper based sensors although it is a standard technique for colorimetric analysis of transparent samples of PDAs [15]. The related UV reflectance technique also did not give reproducible measurements for these rough surface samples. We thus opted to use a commercial photo scanner, which has a capability of wide image area capturing that gave more reproducible color data.

The RGB color system has been successfully used to analyze digital images of various colorimetric paper-based sensors [12,16]. The color images of the PDA sensors were thus converted to the RGB values by an image-processing program. With the numerical RGB data in hand, we would also like to propose here a method to translate the RGB values for sensitivity evaluation of the PDA paper-based sensors. The R, G and B values represent the extent of the red, green and blue components in the image. The values are varied from 0 to 255 that the greater the value is the higher the extent of the hue. For better comparison of the

colorimetric responses, the effects from the background light and color depth were evened out by using the percentage value of each RGB component calculated according to the following equation below, instead of its absolute value.

$$\%R \text{ (or \%G or \%B)} = (R \text{ (or } G \text{ or } B))/(R + G + B) \times 100$$

The plot of %R and %B against the UV dose clearly showed the increase of %R in the expense of %B (Figure 3) while %G remained relatively constant (Figure S17). The small error bars in the plots confirmed high reproducibility of the indicator preparation and color measurement.

To apply the RGB values for the sensitivity evaluation, we assigned the UV dose required at the intersection between %R and %B curves as the color transition UV dose. According to this assignment, the color transition point corresponds to a purple color. The diacetylene that turns to this color with less UV exposure dose is more UV sensitive. For examples, TCDA, ETCDP and ETC DPP required the exposure doses of $780 \pm 52 \text{ mJ/cm}^2$, $264 \pm 32 \text{ mJ/cm}^2$ and $130 \pm 9 \text{ mJ/cm}^2$, respectively, that represent the sensitivity order of TCDA < ETCDP < ETC DPP. The UV doses required for color transition of all paper-based sensors from all 12 diacetylene monomers were determined (Table S1) and plotted into a bar chart as shown in Figure 4. Within the series of the same head group, the diacetylenes with shorter alkyl chain (lower n or m numbers), either between the diyne and carboxyl group or in the lipid tail, required lower UV doses to cause the blue-to-red color transition indicating their greater UV sensitivity. The photo-induced thermochromism has been proposed for the blue-to-red color transition of several PDAs under prolong UV exposure [17]. In thermochromism, the role of the alkyl side chains on the temperature sensitivity has been attributed to the increase of their hydrophobic interaction, which in turn stabilizes the π -conjugated backbone [4,15,18]. We therefore conducted a thermochromism study of the blue PDAs obtained from all 12 monomers (see supporting information for detail experiments of the thermochromism

study). The blue-to-red color transition temperatures of the PDAs, depicted as the dots in Figure 4, within each series gave the same trend with the color transition UV doses. The results suggested that, the photo-induced thermochromism is responsible for the sensitivity trend of the PDAs with the same side chain head groups observed during the UV irradiation. Comparing between the series of different head groups, the UV doses required for the color transition of the fatty acid series (PCDA, TCDA, NDDA and ODDA) are generally greater than those of the corresponding monopropanamide (EPCDP, ETCDP, ENDDP and EODDP) and dipropanamide (EODDPP, ENDDPP, ETC DPP and EPCDPP). Interestingly, the comparison of UV sensitivity between the series is not well correlated with their thermal sensitivity. For example, the blue-to-red transition of EPCDP, a monopropanamide derivative, was observed at a much lower UV dose comparing with TCDA while both of them showed very similar color transition temperature. This difference is even more pronounced when comparing EPCDPP, a dipropanamide derivative, with TCDA; the less thermally sensitive EPCDPP is more UV sensitive than TCDA. The results demonstrated that the color transition caused by UV irradiation is not solely driven by the photo-induced thermochromism. The blue-to-red transition during the UV irradiation of some PDAs has also been attributed to the conformational change caused by the propagation of the polymer chain [19]. The orientation and strength of hydrogen bonding among the head groups in the molar self-assemblies of the diacetylene amido lipids are likely to be quite different from those of the diacetylene containing carboxylic acid groups. Since the blue-to-red transition of the amide series is faster in the UV irradiation but not in the heating process, their molecular assemblies are thus more readily to undergo the conformational alteration during the topopolymerization process.

Scanning electron microscopy (SEM) of the blue and red PDA coated on cellulose fibers of the filter paper strips revealed interesting microscopic phenomena. The diacetylene

containing carboxylic acid head group showed PDA film rupture upon the color transition from blue to red (Figure 5a and d). However, no significant change was observed for the PDAs obtained from the diacetylene containing mono- and diamide head groups. Similar results were also observed in the thermochromic color transition (Fig. S25). The rupture denoted that the blue-to-red color transition was accompanied with a major and sudden change in the molecular assembly [20]

Conclusion

At room temperature, both photo-induced thermochromism and direct photochromism cooperate in the UV-induced blue-to-red color transition of the PDAs generated from the diacetylene lipids containing carboxylic acid and amide head groups. The coarse tuning of the UV sensitivity was achieved by converting the lipid head group from carboxylic acid to the amide or diamide, which ably affects the photochromism sensitivity, while the fine tuning was possible by varying the aliphatic chain length, which progressively affects the photo-induced thermochromism sensitivity. The conversions of the head groups from the carboxylic acid to the amide groups alter the intermolecular interaction and orientation in the monomer assembly. The monomer structures, sensor preparation and evaluation techniques devised in this work should serve as guidelines for systematic study of solid-state chromic materials toward the development of economical and reliable colorimetric sensors.

- 15 ในปีค.ศ. 2008 Friedman และคณะ [Lipid/polydiacetylene films for colorimetric protein surface-charge analysis, *Anal. Chem.* **2008**, 80, 7804–7811] ได้เสนอวิธีวิเคราะห์หาประจุบนพื้นผิวของโปรตีนวิธีใหม่ โดยใช้ระบบประมวลผลทางภาพ โดยการปรับแรงกระทำระหว่างโปรตีนกับ poly(10, 12-tricosadiynoic acid) ในรูปฟิล์มบนแผ่นกระจกโดยวิธีแลง-เมียร์-เชเฟอร์(Langmuir-Shaefer method)

- 20 เมื่อเติมโปรตีนที่มีประจุบวก โปรตีนจะไปจับกับประจุลบของหมู่คาร์บอกซิลิกของพอลิไดแอเซทีลีน ทำให้เกิดการเปลี่ยนสีจากสีน้ำเงินเป็นสีแดง และสามารถวิเคราะห์เชิงปริมาณได้โดยวัดค่าความเข้มสีแดงที่เพิ่มขึ้นในรูป โดยรายงานผลเป็น %RCS ซึ่งหาได้จากสมการ

$$\%RCS = \frac{(r_{sample} - r_0)}{r_{max} - r_0} \times 100\%$$

- 25 โดยที่ r_{sample} คือ ค่าสีแดงของสารตัวอย่าง

r_0 คือ ค่าสีแดงเริ่มต้นของแบล็ค(Blank)

$$net\ RCS = RCS_1 - RCS_0$$

ทำให้สามารถระบุเอกลักษณ์ของประจุบนพื้นผิวของโปรตีนได้

ในปี 2012 Eaidkong และคณะ ได้ศึกษาเกี่ยวกับพอลิไดอะเซทิลีนอินดิเคเตอร์เพื่อใช้ในการตรวจวัดไอของตัวทำละลายอินทรีย์ ซึ่งได้นำระบบสี RGB มาใช้ในการบอกปริมาณของการเปลี่ยนแปลงของสี จากนั้นนำไปใช้แยกชนิดของตัวทำละลายอินทรีย์โดยใช้โปรแกรมทางสถิติพีซีเอ (PCA, principal component analysis) ซึ่งวิธีนี้ได้ใช้ค่า RGB โดยตรง จึงอาจจะมีผลของแสงสถานะแวดล้อม ทำให้ผลวิเคราะห์ที่ได้ผิดพลาดได้

ในปี 2012 Abdel-Fattah และคณะ [A new label dosimetry system based on pentacosadienoic acid monomer for low dose applications, *Radiation Physics and Chemistry*, 2012, 81, 70-76] ได้นำระบบสี Lab มาใช้ในการบอกปริมาณการเปลี่ยนแปลงของพอลิไดอะเซทิลีนที่จะนำมาใช้เป็นอินดิเคเตอร์ในการตรวจวัดปริมาณรังสีแกมมา โดยใช้ช่องสี b ที่ลดลงเป็นตัวบอกปริมาณของสีน้ำเงินที่เพิ่มขึ้น

จากงานวิจัยและสิทธิบัตรเกี่ยวกับการใช้การประมวลผลทางภาพมาใช้ในการวิเคราะห์เชิงปริมาณของอินดิเคเตอร์ ซึ่งการเปลี่ยนแปลงสียังไม่สามารถบอกจุดเปลี่ยนสีที่แม่นยำ และต้องใช้เครื่องมือที่มีราคาแพง

15 **ลักษณะและความมุ่งหมายของการประดิษฐ์**

การประดิษฐ์นี้ได้นำเสนอวิธีที่ใช้ในบอกจุดเปลี่ยนแปลงสีด้วยเทคโนโลยีประมวลผลภาพ เพื่อใช้กับอินดิเคเตอร์ที่มีการเปลี่ยนแปลงสีสำหรับการตรวจวัดต่าง ๆ โดยจะเก็บภาพการเปลี่ยนแปลงสีของอินดิเคเตอร์ ด้วยกล้องถ่ายภาพกล้องเว็บแคมหรือสแกนเนอร์ จากนั้นทำการหาค่าสี RGB และนำไปคำนวณเป็นค่าเปอร์เซ็นต์ของแต่ละองค์ประกอบสี และนำไปแสดงผลให้อยู่ในรูปกราฟเส้น ซึ่งจะให้ผลที่ระบุช่วงการเปลี่ยนสีที่แคบ ชัดเจนมากขึ้น มีความแม่นยำสูง และลดผลกระทบจากแสงแวดล้อมได้ กระบวนการทำไม่ซับซ้อน

คำอธิบายรูปเขียนโดยย่อ

- รูปที่ 1 แสดงกราฟเปอร์เซ็นต์คัลเลอร์ิเมตริกเรสปอนส์ (Colorimetric Response, %CR) ของการเปลี่ยนแปลงสีของอินดิเคเตอร์ที่ใช้ในการตรวจไวรัส
- 25 รูปที่ 2 แสดงอุปกรณ์และส่วนประกอบเพื่อการตรวจวัดการเปลี่ยนสีของอินดิเคเตอร์
- รูปที่ 3 แสดงขั้นตอนการตรวจวัดการเปลี่ยนแปลงสีของอินดิเคเตอร์โดยการประมวลผลภาพ
- รูปที่ 4 การเปลี่ยนสีของอินดิเคเตอร์ตรวจวัดอุณหภูมิ
- รูปที่ 5 แสดงกราฟระหว่างเปอร์เซ็นต์สีกับอุณหภูมิ
- รูปที่ 6 การเปลี่ยนสีของอินดิเคเตอร์ตรวจวัดปริมาณรังสียูวี
- 30 รูปที่ 7 แสดงกราฟระหว่างเปอร์เซ็นต์สีกับปริมาณรังสียูวี
- ตารางที่ 1 แสดงค่าองค์ประกอบสีของอินดิเคเตอร์กับอุณหภูมิ
- ตารางที่ 2 แสดงค่าเปอร์เซ็นต์องค์ประกอบสีของอินดิเคเตอร์กับอุณหภูมิ
- ตารางที่ 3 แสดงค่าองค์ประกอบสีของอินดิเคเตอร์กับปริมาณรังสียูวี
- ตารางที่ 4 แสดงค่าเปอร์เซ็นต์องค์ประกอบสีของอินดิเคเตอร์กับปริมาณรังสียูวี

การเปิดเผยการประดิษฐ์โดยสมบูรณ์

- 5 เริ่มจากการนำภาพที่ได้จากสแกนเนอร์ กล้องถ่ายภาพ หรือกล้องเว็บแคม มาประมวลผลทางภาพด้วยระบบสี RGB ซึ่งจะทำให้ได้องค์ประกอบของสีต่าง ๆ จากนั้น จะทำการคำนวณเปอร์เซ็นต์องค์ประกอบสีต่าง ๆ ดังสมการ

$$\%R = \frac{R}{R+G+B} \times 100 \quad (1)$$

$$\%G = \frac{G}{R+G+B} \times 100 \quad (2)$$

$$\%B = \frac{B}{R+G+B} \times 100 \quad (3)$$

- 10 ซึ่งการคำนวณเป็นเปอร์เซ็นต์ มีข้อดีคือ ช่วยลดผลของแสงแวดล้อม เพราะถ้าใช้ค่า RGB จริงจะให้ค่าที่ผันผวนมากตามปริมาณของแสงแวดล้อม

- จากนั้นนำค่า %R %G และ %B ไปสร้างกราฟเส้น จะได้ผลแสดงดังรูปที่ 5 จากกราฟเป็นอินดิเคเตอร์วัดอุณหภูมิที่เปลี่ยนสีจากสีน้ำเงินเป็นสีแดงเมื่ออุณหภูมิเพิ่มขึ้น ซึ่งเราจะกำหนดจุดสีม่วง (%R = %B) เป็นจุดเปลี่ยนสีของอินดิเคเตอร์ ซึ่งจะทำให้สามารถหาค่าอุณหภูมิที่ทำให้อินดิเคเตอร์เกิดการเปลี่ยนสี โดยดูจากจุดตัดระหว่าง %R และ %B

ตัวอย่าง

ตัวอย่างที่ 1 วิธีการระบุจุดเปลี่ยนสีของพอลิ(ลิบ, ลิบสอง เพนตะโคสะไดโอนโนอิกแอซิด) (poly(10,12-pentacosadiynoic acid) ,PCDA) อินดิเคเตอร์เพื่อใช้ในการตรวจวัดอุณหภูมิ

- 20 พอลิ(ลิบ, ลิบสอง เพนตะโคสะไดโอนโนอิกแอซิด) ถูกเตรียมเป็นอินดิเคเตอร์ กระจกซึ่งจะถูกนำมาติดกับด้านข้างของบีกเกอร์ขนาด 600 mL ซึ่งบรรจุน้ำอยู่ 400 mL อินดิเคเตอร์จะถูกให้ความร้อนจาก 30 °C ถึง 90 °C และถ่ายภาพโดยใช้กล้องเว็บแคม ที่ต่อกับคอมพิวเตอร์

จากนั้นนำรูปที่ได้จากกล้องเว็บแคม มาประมวลผลทางภาพเพื่อหาค่าสี RGB ดังแสดงในตารางที่ 1 จากนั้นนำไปคำนวณหาค่า %R, %G, และ %B ดังแสดงในตารางที่ 2

- 25 จากตารางที่ 2 จะเห็นได้ว่าค่า %G ก่อนข้างคงที่ เพราะการเปลี่ยนสีของอินดิเคเตอร์เป็นการเปลี่ยนจากสีน้ำเงินเป็นสีแดง ดังนั้นเราจึงสามารถใช้จุดที่ %R เท่ากับ %B เป็นจุดเปลี่ยนสีของอินดิเคเตอร์ ซึ่งการหาจุดตัดจะหาจากสร้างสมการเส้นตรงสองเส้น ตามรูปที่ 5 จุดตัดจะอยู่ระหว่างอุณหภูมิ 70-75°C ซึ่งที่ 70°C จะมีค่า %R, %G, %B = 35.8, 27.2, 37.0 และที่ 75°C จะมีค่า %R, %G, %B = 41.4, 26.8, 31.8 ซึ่งจะนำ %R ที่ 70°C และ 75°C มาสร้างเป็นสมการเส้นตรงตามสมการ
- 30

$$y = ((y_2 - y_1)/(x_2 - x_1))x + c$$

$$x_1 = 70, y_1 = 35.8, x_2 = 75, y_2 = 41.4$$

$$\text{จะได้ว่า } y = ((41.4 - 35.8)/(75 - 70))x + c$$

$$y = 1.12x - 42.6$$

- 5 และในทำนองเดียวกันสร้างเส้นตรงจาก %B อีกหนึ่งเส้นจาก $x_1 = 70, y_1 = 37.0, x_2 = 75, y_2 = 31.8$

จะได้สมการ

$$y = -1.05x + 110.2$$

นำ สมการเส้นตรงสองเส้นมาหาจุดตัดโดยแก้สมการหาค่า x และ y จะได้จุดตัดที่ $x = 70.5, y = 36.4$
 หมายความว่า พอลิไดเอเซทิสีนอินดิเคเตอร์ชนิดนี้สามารถเปลี่ยนเป็นสีม่วงเมื่อมีอุณหภูมิ 70.5°C

- 10 ตัวอย่างที่ 2 เอทิล-3-ไตรโคสะ-ลิบ, ลิบสอง-ไดโอนามิโดโพรพาโนเอต poly(Ethyl-3-tricoso-10,12-diyamidopropanoate) อินดิเคเตอร์เพื่อใช้ในการตรวจวัดปริมาณรังสียูวี

เอทิล-3-ไตรโคสะ-ลิบ, ลิบสอง-ไดโอนามิโดโพรพาโนเอตถูกเตรียมเป็นอินดิเคเตอร์
 กระจกชาย ซึ่งจะถูกฉายแสงด้วยรังสียูวี 254 nm ที่เวลาต่าง ๆ
 จากนั้นเก็บข้อมูลโดยใช้สแกนเนอร์ที่ต่อกับคอมพิวเตอร์

- 15 จากนั้นนำรูปที่ได้จากสแกนเนอร์ นำมาประมวลผลทางภาพเพื่อหาค่าสี RGB
 ดังแสดงในตารางที่ 3 จากนั้นนำไปคำนวณหาค่า %R, %G, และ %B ดังแสดงในตารางที่ 4
 จากนั้นหาจุดตัดจะหาจากสร้างสมการเส้นตรงสองเส้น ตามรูปที่ 7
 จุดตัดจะอยู่ระหว่างปริมาณรังสียูวี $252\text{--}336\text{ mJ/cm}^2$ ซึ่งที่ 252 mJ/cm^2 มีค่า %R, %G, %B = 33.2,
 30.5, 36.4 และที่ 336 mJ/cm^2 มีค่า %R, %G, %B = 39.1, 28.9, 32.1

- 20 ซึ่งมาสร้างเป็นสมการเส้นตรงตามสมการ

$$y = ((y_2 - y_1)/(x_2 - x_1))x + c$$

$$x_1 = 252, y_1 = 33.2, x_2 = 336, y_2 = 39.1$$

$$\text{จะได้ว่า } y = 0.07x - 15.5$$

และในทำนองเดียวกันสร้างเส้นตรงจาก %B อีกหนึ่งเส้นจาก $x_1 = 252, y_1 = 36.4, x_2 = 336, y_2 = 32.1$

- 25 จะได้สมการ

$$y = -0.05x + 49.3$$

นำ สมการเส้นตรงสองเส้นมาหาจุดตัดโดยแก้สมการหาค่า x และ y จะได้จุดตัดที่ $x = 278.6, y = 35.37$

หมายความว่า

พอลิไดแอเซทิลีนอินคิเตอร์ชนิดนี้สามารถเปลี่ยนเป็นสีม่วงเมื่อได้รับปริมาณรังสียูวี 278.6 mJ/cm²

5 **วิธีการในการประดิษฐ์ที่ดีที่สุด**

ตามที่ได้กล่าวไว้แล้วในหัวข้อการเปิดเผยการประดิษฐ์โดยสมบูรณ์

การใช้การประดิษฐ์ในการผลิตทางอุตสาหกรรม หัตถกรรม เกษตรกรรม หรือ พาณิชยกรรม

อุตสาหกรรม พาณิชยกรรม

บทสรุปการประดิษฐ์

- การประดิษฐ์นี้เกี่ยวข้องกับการนำเสนอวิธีระบุจุดเปลี่ยนสีของอินดิเคเตอร์โดยใช้เทคโนโลยีประมวลผลภาพ โดยการนำภาพที่ได้จากเครื่องสแกนเนอร์ กล้องถ่ายภาพหรือกล้องเว็บแคม มาหาค่าสีโดยใช้ระบบสี RGB จากนั้นจะนำค่าองค์ประกอบสีต่าง ๆ มาคำนวณเป็นเปอร์เซ็นต์เพื่อลดผลกระทบของแสงแวดล้อม และสร้างเป็นกราฟ เพื่อหาจุดตัดของระหว่างองค์ประกอบของสี ซึ่งถือว่าเป็นจุดเปลี่ยนแปลงของอินดิเคเตอร์
- 5

ข้อถ้อยสิทธิ

1. การระบุจุดเปลี่ยนแปลงสีของอินดิเคเตอร์โดยใช้เทคโนโลยีประมวลผลภาพที่ประกอบด้วย
 - สแกนเนอร์(200) กล้องถ่ายภาพหรือกล้องเว็บแคม(240) สำหรับการรับภาพอินดิเคเตอร์ (ที่ต้องการหาการเปลี่ยนสี)
 - หน่วยประมวลผล (220) ซึ่งรับข้อมูลภาพที่ได้จากสแกนเนอร์ กล้องถ่ายภาพหรือกล้องเว็บแคมที่ใช้ในการบันทึกการเปลี่ยนแปลงสี
 - ส่วนแสดงผล(230) สำหรับแสดงผลการวิเคราะห์ที่ได้จากหน่วยประมวลผลดังกล่าว โดยกระบวนการหาจุดเปลี่ยนแปลงสีของอินดิเคเตอร์ดังกล่าว มีลักษณะเฉพาะคือ การนำภาพที่ได้มาประมวลผลเป็นค่าสี RGB และคำนวณให้อยู่ในรูปเปอร์เซ็นต์ เพื่อลดผลกระทบของแสงแวดล้อม และนำไปสร้างเป็นกราฟเส้นโดยกำหนดให้ค่าเปอร์เซ็นต์ของสีที่เท่ากันเป็นจุดเปลี่ยนแปลงของอินดิเคเตอร์
2. ตามข้อถ้อยสิทธิที่ 1 จากกราฟ ที่จุดที่มีค่าสีเท่ากัน สามารถใช้กับสารที่เปลี่ยนแปลงอื่น ๆ หรือการตรวจวัดการเปลี่ยนแปลงอื่น ๆ ได้
3. ตามข้อถ้อยสิทธิที่ 1 สามารถใช้ระบบสีอื่น ๆ นอกจาก RGB ได้
4. ตามข้อถ้อยสิทธิที่ 1 สามารถใช้กับค่าสีโดยไม่ต้องคำนวณเป็นเปอร์เซ็นต์
5. ตามข้อถ้อยสิทธิที่ 1 สามารถใช้กับอุปกรณ์วัดค่าสีต่าง ๆ โดยไม่ได้ผ่านหน่วยประมวลผลที่เป็นคอมพิวเตอร์

VITAE

Mr. Watcharin Ngampeungpis was born on April 10, 1983 in Bangkok, Thailand. He graduated with Bachelor's Degree in Chemistry from Faculty of Science, Chulalongkorn University in 2005. For Master 's Degree, he graduated in Inorganic Chemistry in Department of Chemistry, Faculty of Science, Chulalongkorn University in 2008. After graduated in Master degree, he worked at Mahaphant fiber-cement public company as a researcher and then he continued his study in a Ph.D degree in program of Petrochemistry at Chulalongkorn University in academic year and completed in 2012. His current address is 162 Soi Wachirathumsathit 28, Sukhumvit 101/1 road, Bangna, Bangna, Bangkok, 10260.
