KULISARA MARUPANTHORN : CLONING AND SEQUENCING OF 3ABC GENE OF FOOT AND MOUTH DISEASE VIRUS TYPE O FROM A THAI PIG ISOLATE FROM RATCHABURI PROVINCE IN 2005. ADVISOR : ASSOC. PROF. ATHIPOO NUNTAPRASERT, D.V.M., Ph.D., 61 pp.

Foot and mouth disease (FMD) is an important epidemic disease of swine in Thailand. It causes negative effect on swine production and also creates export trade restriction. Consequently, the economic loss is enormous in swine industries. The major type of Foot and mouth disease virus (FMDV) found in Thailand and has been recently isolated from an outbreak in 2005 is FMDV type O. To control this disease is to distinguish the naturally infected swine from the vaccinated ones. In this study, viral RNA was extracted from vesicular fluid and erosion tissue found in coronary band of hoof in FMD infected pigs from Ratchaburi province in 2005. The first strand of FMDV-cDNA was synthesized by reverse transcription reaction. FMD Type O was confirmed by PCR technique using the O-1C_{124} primer set. Then, the full length of 3ABC gene was amplified by using PCR technique. The PCR products of 3ABC gene were cloned into pET160/GW/TOPO® vector. In addition, the nucleotide sequences were analyzed and compared with previously reported 3ABC nucleotide's databases. The results showed that five clones of 3ABC expression vectors were successfully collected (1,303 bp). As a result, phylogenetic tree analysis of 3ABC nucleotides revealed that this gene of FMDV type O isolated from pig in Ratchaburi province in 2005 had 100 % homology to those of FMDV type O strain Tibet /CHA/99 (Genbank accession number is AJ539138).

ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to Associate Professor Dr. Athipoo Nuntaprasert, my advisor. I am sincerely grateful for all he has taught and advised. I am also truly thankful for his excellent instruction, advice, indispensable help, encouragement and criticism throughout the period of this study. Working under his supervision is very impressive.

My gratitude is also extended to Associate Professor Ratanaporn Brahmasa, Associate Professor Dr. Supol Luengyosluechakul, Associate Professor Dr. Kanisak Oraveerakul and Mrs. Jarunee Satra for serving as the members of my thesis committee, for their available comments and also useful suggestions.

Thanks are also expressed to all staff members and my friends of the Department of Veterinary Medicine for their help in laboratory. Special thanks are also extended to Manan Wongserepipatana (nong Ple), Nawin Suesutthajit (nong Win), Budsabha Thonghung (nong Tak), Pathamaporn Jarameechai (nong Pu), Chalinee Wiwatana (nong Petch), Chommanart Thongkittidilok (nong Gift), and Jariya Rungsrithong (nong Taiy) for their helps, suggestions, kindness, and friendships.

I would like to thank my best friends; Natthaporn Dungdee (Aew), Boondharika Krajangwong (Yui), Chanon Ekkapobyotin (Big), and Thanida Haetrakul (Na) for their lovely and encouragement throughout my study period and my life.

I wish to acknowledge to the Rajamangala University of Technology Tawan-ok and Rajamangala University of Technology Suwannaphoome for my financial support.

Finally, I would like to express my deepest gratitude to my parent, my younger brother, my family and my pet for their unlimited love, understanding, cheerfulness and encouragement.

CHAPTER I

INTRODUCTION

Foot and mouth disease (FMD) is an acute, highly contagious and economically devastating viral disease of cloven-hoofed animals. It plays an important role in livestock and causes economic loss due to lower production and international trade restriction. Currently, this disease is present in two-thirds of the OIE (Office International des Epizooties) member countries where it creates severe economic problems and provides a reservoir of virus ready to spread into virus free areas. A recent study on the economic impact of a FMD outbreak in the United States concluded that larger impact of this disease caused the loss of export markets and consumer fears (Paarlberg et al., 2002). Similar conclusions have been reported from an outbreak of FMD in Thailand (Linchongsubongkoch, 2003).

Foot and mouth disease virus (FMDV) is divided into 7 distinct serotypes (A, Asia1, C, O, SAT1, SAT2 and SAT3) based on complete loop of cross protection. Type O, A and Asia1 are considered as endemic serotypes in domestic animals in Thailand (Office International des Epizooties, 2005) and the most of FMDV infection in pig is FMDV type O (Knowles et al., 2005). In Thailand, a nationwide FMD epidemic is ongoing under control strategies. The number of FMDV type O infected pig was 261 pigs and dead pigs was 111 pigs in 2004 (Department of Livestock Development: DLD, 2004[a]; 2004[b]). In 2005, the number of FMDV type O infected pig was 349 pigs and dead pigs was 12 pigs in 2005 (DLD, 2005[a]; 2005[b]; 2005[c]). There was no officially reported in 2006 (DLD, 2006). However, the number of FMDV infected carrier pig has never been reported in Thailand and a little known about the study of FMD typing from field isolated samples.

FMDV is a single-stranded RNA virus belonging to the genus *Aphtovirus* in the family *Picornaviridae*. This genus also includes equine rhinitis A virus (ERAV), previously known as equine rhinovirus type 1 (Hartley et al., 2001). Like other picornaviruses, FMDV genome consists of single-stranded linear RNA with an approximate size of 8 kb (Forss et al., 1984; Kweon et al., 2002). The RNA of FMDV has a single open reading frame (ORF) encoding one long polypeptide that is processed to 12 viral proteins. Among the viral proteins induced by FMDV infection, four proteins (VP1–4) are the major subunit of viral capsid. Although the other proteins like L, 2A–C and 3A–D are not part of capsid structure, they also

induce antibody responses in infected animals (Berger et al., 1990; Diego et al., 1997; Lubroth and Brown., 1995; Malirat et al., 1998; Rodriguez et al., 1994; Silberstein et al., 1997)

There are three particular features of FMD which make rapid, sensitive, and specific laboratory tests essential for diagnosis. Firstly, it is the most contagious disease of cloven-hoofed animals; hence it has the potential for explosive spread in susceptible livestock populations. Secondly, it is acknowledged as the most serious constraint to international trade in livestock and animal products. Thirdly, other viruses can produce symptoms which are clinically indistinguishable from FMD. Therefore, necessary laboratory investigation for a definitive diagnosis is required (Reid et al., 2001). Traditionally, primary virus diagnosis of FMD is carried out by complement fixation test (CFT) or by enzyme linked immunosorbent assay (ELISA) on epithelial tissue suspension or vesicular fluid of clinical samples. These suspensions are simultaneously inoculated into cell culture and the specificity and serotype of isolated viruses is further established by the CFT or the ELISA, sandwich ELISA for FMDV typing and liquid phase block ELISA for screening of FMDV antibody titer. However, these diagnostic methods cause delay many times, have high cost, and need intensive labor. Recent advances in molecular biology have resulted in the development of techniques such as reverse-transcriptase polymerase chain reaction (RT-PCR) for detection of FMD genomic RNA in culture fluid or in clinical samples (Remond et al., 2002). Although various protocols have been tested, none of them is separately used for primary diagnosis but for conjunction with the standard methods.

FMD Vaccine is used for control outbreaks of disease and is a dead preparation of whole virus particles in an oil or aluminum hydroxide/saponin adjuvant. There will be no replication of the virus following vaccination, and the vaccinated animal will develop antibodies to structure of viral capsid proteins. Some of virus can neutralize, and protect it from subsequent infection. There is no viral replication and no expression of the non structural proteins (NSPs). The animal will not develop antibodies particularly against 3D to those proteins. Although some vaccines contain low levels of these NSPs depending on the manufacturing process, those vaccines stimulate low antibody response to the NSPs especially more obvious in multiply vaccinated animals. The 3D gene encodes for the viral polymerase, and antibody response to this protein were detected in the agar gel immuno-diffusion VIAA (virus infection associated antigen) test (Kitching, 2004).

Recombinant antigens are brought into attention because of their specificity and reproducibility of quality of prepared antigens. Recombinant antigen based on serologic tests are widely used in screening for FMDV infection in cattle, but use of recombinant proteins for serodiagnosis of FMDV in pig has not been widely investigated. Many diagnostic tests have been developed to distinguish infected animals from vaccinated animals using detection of antibodies to the NSPs especially in 3ABC gene (Kweon et al., 2003; Official of Agricultural commodity and food standard, 2004). It is also known that currently available inactivated vaccines mainly consist of capsid proteins and induce weak antibody responses to NSPs in vivo after vaccination, whereas infected animals produce antibodies to both structural and NSPs proteins (Diego et al., 1997; Mackay et al., 1998). Assays demonstrating antibodies against NSPs have potential to differentiate infected animals from those of merely vaccinated animals (Sorensen et al., 1998; Clavijo et al., 2004[b]).

Furthermore, Clavijo et al. (2004[b]) reported that antibody response to 3ABC protein in cattle, sheep and pigs was detected as early as 7 dpi. Eble et al. (2007) reported antibody response to 3ABC protein was detected in 8 dpi in vaccinated pig. The profiling ELISA showed that antibody response to 3ABC appeared early after infection and antibody to 3ABC could be detected for longer than antibody to any other NSPs (Mackay et al., 1998). Thus, the several ELISAs have been developed to distinguish infected animals from those of vaccinated animals by using 3ABC protein.

The advent of biotechnology has made possible immunoassay to 3ABC recombinant protein by enabling their production in large quantities through in vitro expression in a variety of prokaryotic or eukaryotic vectors. A wide range of 3ABC gene had been expressed as fusion proteins in *E. coli* or using baculovirus vector in insect cells (Remond et al., 2002). This research cloned 3ABC gene into *E. coli* which had a simple cultivation and large amounts of recombinant protein but lacked eukaryotic post-translational modifications (Turner et al., 2005). Fortunately, the post-translational modification is not nessary for the 3ABC gene (La Torre et al., 1980).

Therefore, the purposes of this research are to clone 3ABC gene of FMDV type O isolated from a Thai pig in Ratchaburi province in 2005 into a bacterial expression vector, to study the sequence of 3ABC gene and the possibility of gene variation. The 3ABC gene was amplified from FMDV cDNA by using polymerase chain reaction (PCR) with primers specific for 3ABC gene of FMDV type O. The plasmid pET160/GW/D-TOPO containing sequence of histidine residues was used for constructing a plasmid expressing 3ABC protein.

PCR product and pET160/GW/D-TOPO plasmid were cut with appropriate enzymes and the digested products were ligated. The expression plasmid was transformed into *E.coli.* Single clone was selected and confirmed by using PCR and DNA sequencing. In addition, the obtained sequence was compared and analyzed the homology data with the previously reported 3ABC sequence database from Genbank as follow; O1Campos (Genbank accession number is AJ320488), O1manisa iso87 (Genbank accession number is AY593823), Taiwan97 iso106/112 (Genbank accession number is AY593835), Tibet/CHA/99 (Genbank accession is number AJ539138), and UK2001 iso84 (Genbank accession number is AY593836) using Bioedit Sequence Alignment Editor (Hall, 1999) and MEGA version 4.1 (Tamura et al., 2007) softwares.

The sequencing data of 3ABC gene is the first report in Thailand. It is compared with other 3ABC gene of FMDV type O database from Genbank. In addition, both data and techniques used in this study can be applied to further studies involving cloning of 3ABC FMDV gene in the other type of FMDV and other virus.

CHAPTER II

REVIEW LITERATURES

1. General characteristics and pathogenesis of FMDV

FMDV is a single-stranded RNA virus belongs to the genus *Aphtovirus* in the family Picornaviridae. The only other member of this genus is equine rhinitis A virus (ERAV) (Grubman and Baxt, 2004). Seven serotypes (A, O, C, Asia 1, and South African Territories 1, 2, and 3) have been identified serologically, and multiple subtypes occur within each serotype (Bachrach, 1968).

Disease is characterized by fever and vesicular erosion on mouth, tongue, muzzle, hooves and udder which leads to salivation and lameness (Figure 2.1). The morbility rate is very high but the mortality rate is low except in very young animals (Linchongsubongkoch, 2003). In young piglets, the infection may be fatal due to myocarditis. Pigs usually become infected by eat FMDV-contaminated feed, direct contact with infected animals, or by being placed into areas that had once housed FMDV-infected animals. However, pigs are much less susceptible to aerosol infection than cattle (Alexandersen et al., 2002), yet they excrete far more aerosolized virus than cattle or sheep. In cattle, the incubation period is depends on the amount of infecting virus and route of infection, but it is generally 2 days or more. The infected animals develop fever, viremia, and lesions on the feet and tongue. Foot lesions are the most common finding in pigs, while lesions at other sites occur less frequently. Tongue lesions are usually small and less noticeable than those of in cattle (Kitching and Alexandersen, 2002). In young piglets, the infection may be fatal due to myocarditis. Initial replication of the virus occurs at the site through which virus gains entry, followed by rapid dissemination to most of the epithelial sites within the animal (Brown et al., 1995). Interestingly, virus can be found at sites where clinical lesions either are not present or do not form (Oleksiewicz et al., 2001). While pigs excrete large amounts of aerosolized virus, recent evidence suggests that much more viral replication takes place in the nasal mucosa than in the lungs (Grubman and Baxt, 2004).

A. B.

Figure 2.1 Generalized lesions in pigs affected with FMDV, field cases. A. lesions are evident along the coronary bands and B. lesions at the snout. Courtesy of Dr. Supol Luengyosluechakul.

The virus replicates to a high titer in epithelial cells, particularly those undergoing repair, and consequently lesions may also be seen on the hocks or elbows of pigs being housed on concrete floor where damage to legs are common. FMDV also destroy the replicating myocardial cells of young susceptible species, resulting in high mortality from heart failure.

Susceptible livestock may be infected by FMDV as a result of direct or indirect contact with infected animals or with an infected environment. When infected and susceptible animals are in close proximity, the aerial transfer of droplets and droplet nuclei is probably the most common mode of transmission. Long-range airborne transmission of virus is an uncommon but important route of infection, requiring the chance combination of particular factors, including (1) the animal species, (2) the number and location of the transmitting and recipient animals, and (3) favourable topographical and meteorological conditions (Alexanderson et al., 2003).

Eventhough FMD infected animals are slaughtered, FMDV still alive in these frozen carcasses until rigor mortis. If some infected products are fed to susceptible species (e.g. pigs), an outbreak of FMD will be likely to occur. There are remain numerous examples of FMD outbreaks initiated through ingestion of FMD virus-infected products by pigs (Kitching, 1998); hence countries frequently maintain strict regulations concerning the heat treatment of pig swill.

FMDV is particularly susceptible to inactivation outside its host, for example exposure to high temperatures, drying or where the pH is <6 or >10. When a carcass is permitted to mature after slaughtering (at 2 °C for 24 h), the lactic acid will kill any virus in the meat by reducing the pH to <6. No reduction in pH occurs in the glands or bone marrow; however, with certain safeguards, it is possible to safely import meat off the bone from countries where FMD is present. Milk from infected animals will also contain large quantities of live virus, sufficient to infect calves or pigs (if the milk is inadequately heat-treated or not diluted by uninfected milk). Semen from infected bulls and ova from infected cows may also be contaminated with live virus (Kitching et al., 2005).

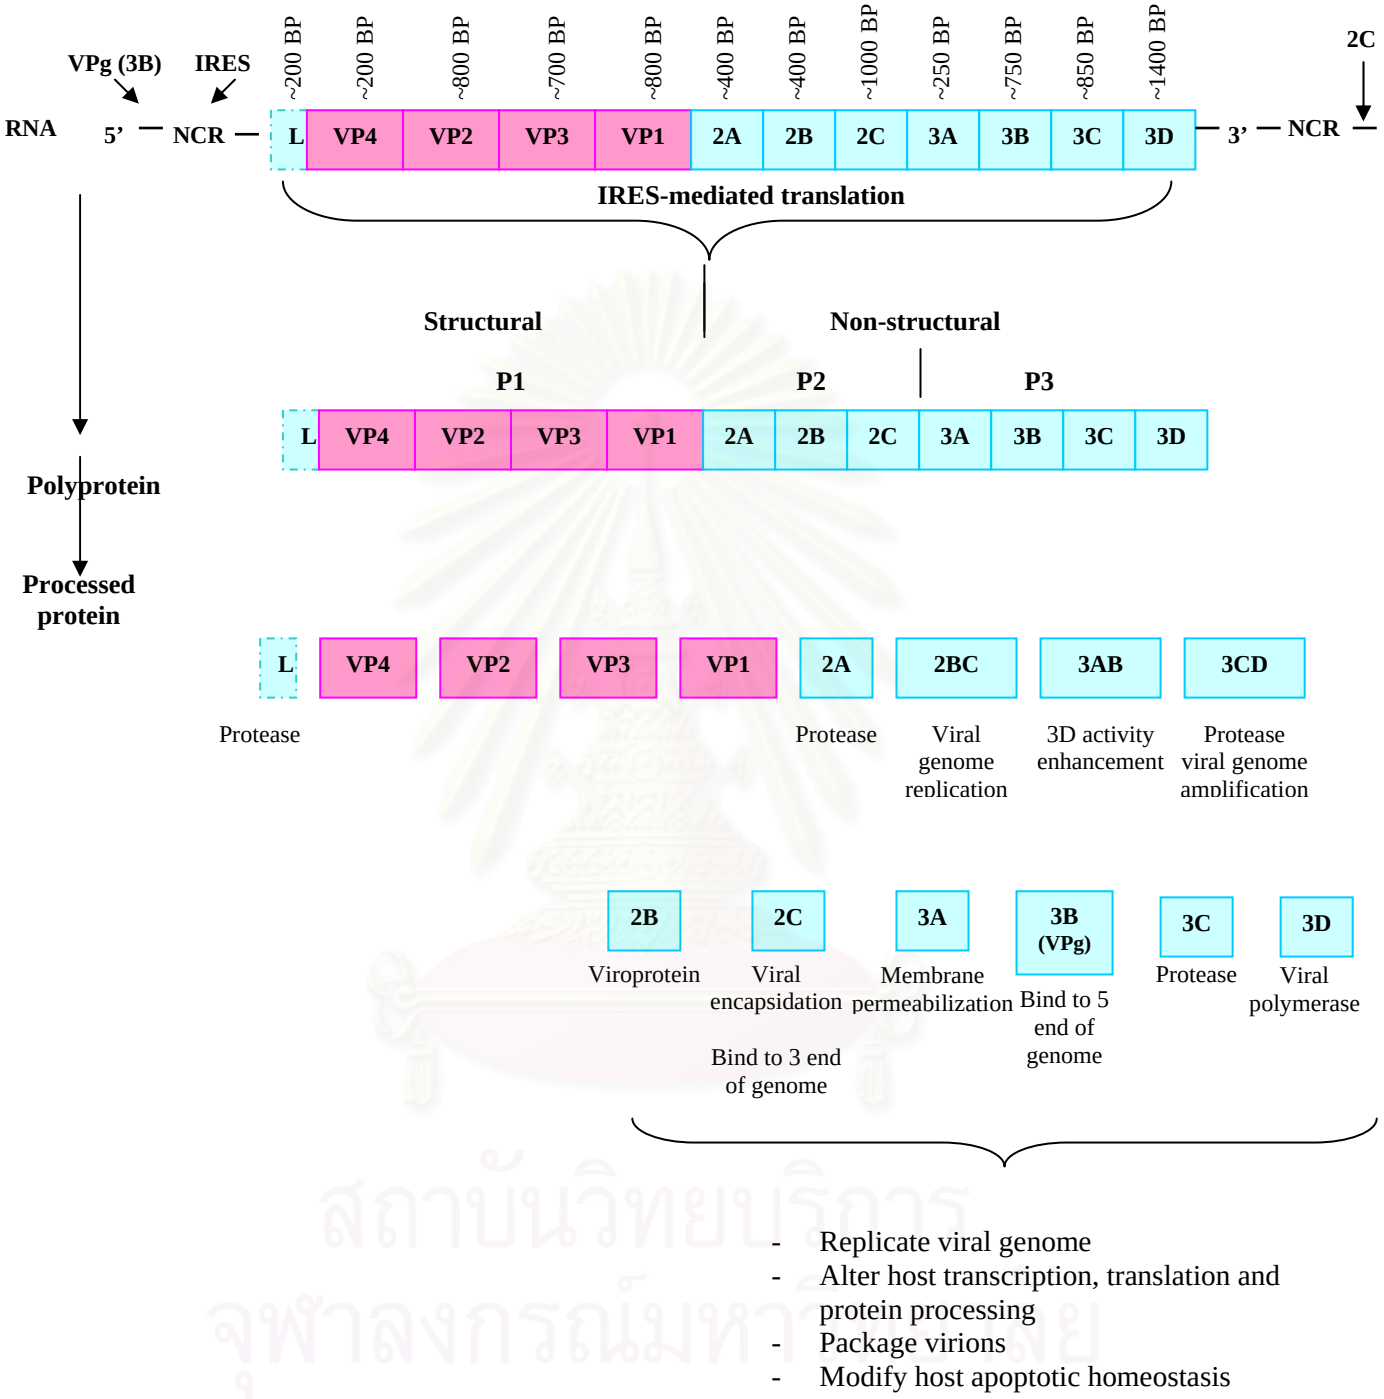
2. Genome organization

The virion is a 140S particle consisting of a single-stranded RNA genome and 60 copies each of four structural proteins (VP1 [1D], VP2 [1B], VP3 [1C], and VP4 [1A]). The FMDV genome has a basic organization similar to those of other members of the *Picornaviridae*, and the nomenclature for the viral proteins was established by Rueckert and Wimmer (1984). Within the virion, there are small amounts of a cleavage precursor of VP2 and VP4, called VP0 (1AB), and one copy of a 23 to 24-amino-acid genome-linked protein, 3B (VPg), covalently bound to the 5' terminus of the RNA (Grubman, 1980). The organization of the viral genome is shown in Figure 2. The RNA is translated as a single long open reading frame (ORF) into a polyprotein, followed by a series of posttranslational proteolytic cleavages to generate both the intermediate and mature structural and NS viral proteins (Grubman et al., 1984; Robertson et al., 1985).

Based on the initial cleavage products, the genome ORF is divided into four regions (Figure 2.2). The 5' end, the L region, which encodes the N-terminal component of the polyprotein, contains two in-frame AUG initiation codons that result in the generation of two L proteins, Lab and Lb (Sangar et al., 1987). While both forms of L are synthesized during in vitro translation of viral RNA (Beck et al., 1983) and in infected cells (Clarke et al., 1985), it has been shown, by using site-directed mutagenesis, that deletion of the second AUG from an FMDV infectious clone abolished viral replication upon transfection of the transcribed RNA into cells, while deletion of the first AUG had no effect on viral replication (Cao et al., 1995). The L protein, a papain-like protease (L^{pro}) (Piccone et al., 1995; Robertsand Belsham, 1995), is autocatalytically cleaved from the polyprotein at its C terminus (Strebel and Beck, 1986).

The L^{pro} also plays a role in inhibition of host protein synthesis and has been identified as a viral virulence factor.

Directly downstream of the L region is the P1 region of the genome (Figure 2.2), encoding the four viral structural proteins VP4, VP2, VP3, and VP1. Following the P1 region is the P2 region (Figure 2.2), encoding three viral NS proteins, 2A, 2B, and 2C, and the P3 region, encoding NSPs 3A, three copies of VPg, $3C^{pro}$, and $3D^{pol}$. Historically the 2A region was considered part of the P2 region; however, genetic and biochemical evidence has shown that the FMDV 2A peptide is cleaved as a P1-2A precursor (Vakharia et al., 1987). $3C^{pro}$ is identified as a viral protease (Klump et al., 1984) and is involved in processing the viral polyprotein, while 3Dpol is the viral RNA dependent RNA polymerase (Cowan and Graves, 1966; Lowe and Brown, 1981; Newman et al., 1979).



- Replicate viral genome
- Alter host transcription, translation and protein processing
- Package virions
- Modify host apoptotic homeostasis

Figure 2.2 Schematic map of the FMDV genome. Also shown are the functional elements of the genome as described in the text and the partial protein cleavage products.

3. Function and application of FMDV genes

The FMDV genome is composed of three parts, the 5′ untranslated region (5′ UTR), the coding region and the 3′ untranslated region (3′ UTR) containing a heteropolymeric segment and a poly (A) tail, which is required for viral replication. FMDV also contains an internal poly(C) tract within the 5′ UTR. After translation, the polyprotein is cleaved into four primary cleavage products: (1) the amino terminal L protease which cleaves at its own carboxyl terminus; (2) P1 (VP1, VP2, VP3, and VP4) - 2A, the precursor of the capsid proteins; (3) 2BC, and (4) P3, which is cleaved to make the replicative or NSPs 3A, 3B, 3C and 3D, the RNA-dependent-RNA polymerase (Belsham, 1993).

The icosahedral symmetrical viral capsid is assembled from the four structural proteins, with VP1 being the most important because of its dual function in cell receptor binding and antigenic determination (Mateu, 1995; Feng et al., 2004) Currently, much research effort has been focusing on the sequence analysis of structural proteins, especially VP1, owing to their dominant roles in antigenic/serotype determination (Kitson et al., 1990). In the intervening years the great deal has been learned about the function of VP1, the principle target sequence for the development of synthetic vaccines, both in its role as the receptor binding ligand of the virus and as an antigenic determinant (Rowlands, 2004).

The VP2, VP3 and VP4 gene are the part of viral capsid, which VP4 is a major protein to stable a viral capsid. L and 2A gene are the major proteinases for hydrolytic cleavage of the polyprotein (Klump et al., 1984; Strebel and Beck, 1986). VP2, VP3, VP4, L and 2A protein are not used in any application. The function of 2B gene is amplifying RNA, inhibit alteration of membrane permeability of cellular exocytosis and rearrange endoplasmid reticulum. The short hairpin RNA targeted to the highly conserved 2B NSP coding region is developed to inhibit replication of multiple serotypes of FMDV (Santos et al., 2005). The function of 2C gene is formation of vesicles, virus encepsidation and RNA binding in RNA replication. The 3A gene has been found to be associated with host alteration (Beard and Mason, 2000; Knowles et al., 2001) and inhibit MHC class I expression (Clavijo et al., 2004[a]). The 3B (VPg) gene, also known as the genome-linked protein, may be involved in priming RNA replication (Wimmer, 1982). The 3C gene is responsible for proteolytic cleavage of the majority of the cleavage sites in the FMDV polyprotein. The 3D gene, the viral RNA-dependent RNA polymerase (RdRp), is responsible for both positive- and negative-sense RNA replication. The recently resolved crystal structure of the poliovirus 3D and other genetic/biochemical analyses suggest that the polymerase might function as a

higher order oligomeric structure (Hobson et al., 2001). The 2C, 3ABC and 3D gene are applied to develop recombinant protein for ELISA test kit to distinguish FMDV vaccinated animals from FMDV infected animals.

In addition, the viral proteinases L, 3C and the 2A oligopeptide discussed previously are the NSPs from the subregion 2BC, with various not well defined functions. The 3A, 3B and 3D genes are primarily involved in polyprotein processing and viral RNA replication, as shown in 2.1.

Table 2.1 Function and application of FMDV genes (Clavijo et al. 2004[a])

Genes	Function	Application
VP1	location of viral antigenic determinant	synthetic peptide FMD vaccine typing of FMDV
VP2	capsid protein	-
VP3	capsid protein	-
VP4	major stability of capsid protein	-
L	host protein synthesis shut off protease cleavage	-
2A	protein cleavage (polypeptide)	-
2B	alteration of membrane permeability inhibition dissociation/rearrangement of endoplasmid reticulum and Golgi RNA amplification	short hairpin RNA inhibit replication of FMDV
2C	formation of vesicle virus encapsidation RNA binding in RNA replication (as 2BC)	recombinant protein antigen for ELISA

3B	primer of RNA synthesis membrane association of replication complexes (as 3AB)	recombinant protein antigen for ELISA
3C	viral protein processing host protein cleavage	recombinant protein antigen for ELISA
3D	RNA dependent RNA polymerase stimulation of RNA synthesis	recombinant protein antigen for ELISA

Upon infection, FMDV elicits a rapid and broad spectrum humoral and cellular response that will protect against infection with homologous and antigenically related viruses. However, immunity to FMDV is thought to be primarily humoral. Infection of susceptible cattle with FMDV results in a rapid rise of serum-neutralizing antibody which can be detected from 4–5 days post-infection and peak at around 28 days. The development of this serum response coincides with resolution of lesions, termination of viremia and the reduction of virus excretion (Doel, 1996). For successful clearance of virus, phagocytosis is assisted by antibody-dependent opsonisation of virus (Rigden et al., 2002). There is evidence of the importance of T helper lymphocytes in the development of the immune response to FMDV infection. However, early events after FMDV infection could prevent the expression of MHC class I peptide complexes on the plasma membrane, which is enhanced by the subsequent virus-induced shut-off of cellular protein synthesis, resulting in a rapid reduction of class I expression in the surface of FMDV infected cells. This inhibitory mechanism affects the presentation of viral peptides by FMDV infected cells to cytotoxic T lymphocytes (Sanz-Parra et al., 1998). The immune response to FMDV is affected by host and viral variables. Host variables include species, breed, age, health, physiological states and FMD immune status. Viral factors including dose, route, volume and viral strain amongst others affect the host response to FMDV infection (Doel, 1996). Both structural and non-structural antigens induce the production of antibodies in infected animals. Infected animals are exposed to NSPs at the time of cytolysis, which because of the replication strategy of the virus are produced in equimolar amounts in infected cattle.

In contrast, vaccinated animals which have not been exposed to replicating virus will develop antibodies only to the viral antigens in the inactivated material. Vaccines consist of semi-purified, chemically inactivated virus and elicit antibodies principally to structural proteins. However, some FMDV vaccines contains NSPs in addition to inactivated virions, and depending on their concentration, they may induce a detectable immune response. The virus-infection associated antigen, VIAA, isolated as a crude antigen extract from tissue culture reacts in agar gel with sera from convalescent animals (Cowan and Graves, 1966). However, VIAA or NSP 3D is present both in the tissue culture from which vaccines are prepared (Donnell et al., 1997) and in the viral particle. Therefore, VIAA antibodies are also present in the sera of vaccinated animals. However, in general no VIAA antibodies are detectable following the initial vaccination, but are not unusual in the sera of animals which have been given multiple vaccinations. This immune response usually disappears within 60–90 days post-revaccination as detected by AGID or 90–180 days post-revaccination when ELISA-3D is used (Donnell et al., 1997). As a consequence, other groups have made efforts

to identify antibodies to the NSPs which could provide a more reliable indicator of infection. In a series of experiments, Berger et al. (1990) analyzed bovine hyperimmune, convalescent sera for FMD-specific antibodies. The sera clearly differed from post-vaccination sera by their capacity to precipitate NSPs 3AB and/or 3C, 2C, and occasionally 3A and 2B. It was concluded that animals which had recovered from FMD would be identified by the presence of antibodies to NSPs. Simultaneous detection of at least two NSP antibodies (excluding the NSP 3D) would be sufficient to demonstrate viral replication (Berger et al., 1990). Further experiments found that the presence of antibodies to the 2C protein, and to a lesser extent to the polypeptide 3ABC, could be used to differentiate the potential carrier convalescent animal from the vaccinated animal and antibodies response to the 2C protein could be detected in cattle up to 365 days after infection (Lubroth and Brown, 1995). The absence of 2C antibodies from the sera of vaccinated animals was explained by the association of this viral protein with cellular debris which is separated from the virus harvest prior to inactivation of the supernatant for vaccine production (Lubroth et al., 1996).

4. The study of NSPs

The diagnostic challenge is to distinguish infected animals, either vaccinated or unvaccinated, from those that have been only vaccinated against the disease since both groups have neutralizing antibodies in their sera. Several ELISAs have been developed to distinguish infected animals from those that have been vaccinated, all based on the detection of antibodies to the NSPs of FMD virus (Table 2.2). Tests to detect antibodies to the polyprotein 3ABC have so far been the most successful. This virus specific NSP has been produced either in recombinant *E. coli* (Strebel and Beck, 1986) or in insect cells infected by appropriately recombinant baculovirus (Sorensen et al., 1998).

Table 2.2 Summary of recombinant NSPs-base diagnostic test

Antigen(s)	Dignostic test	System	Plasmid vector	Remark	Reference

Note: LPB-ELISA, liquid phase blocking ELISA; SLB-ELISA, solid phase blocking ELISA; I-ELISA, indirect ELISA.

In order to reduce the number of false positives due to the presence in the sera of antibodies against expression vector antigens (particularly *E. coli*-derived recombinant proteins), a confirmatory test can be included in the testing format or recombinant proteins can be captured with a specific monoclonal antibody. An Enzyme-linked immunoelectrotransfer blot assay (EITB) has been used as a confirmatory test in combination with a 3ABC ELISA in order to reduce the number of false positives (Bergmann et al., 2000). This approach has been used as part of the FMD eradication program in South America during the past decade. The procedure adopted in sero-surveillance for evidence of infection in Brazil, for example, has been to screen sera from vaccinated cattle using the 3ABC test and retest positive samples by the EITB. If still positive, the animal from which the serum was collected is re-sampled three months later, prior to its next vaccination, and only if this sample is positive by the EITB, are further investigations initiated (Diego et al., 1997) and developed an indirect-trapping ELISA based on the capture of semi-purified 3ABC recombinant protein by a monoclonal antibody.

Another alternative has been the use of peptides for the identification of anti-NSP antibodies identified continuous antigenic determinants within the amino acid sequences of the NSPs 2C and 3ABC. Based on these studies peptides for the 3A and 3B NSP were considered candidates for the specific differentiation of vaccinated from convalescent animals. The 3B protein was chosen because of its greater specificity when compared with the 3A protein that reacted with some sera of vaccinated animals (Shen et al., 1999).

In general, NSP-tests have been predominantly designed to detect NSP antibodies in cattle and are less useful in sheep and pigs. Sheep, in particular, probably because of the frequently subclinical nature of the disease, may fail to develop detectable levels of these antibodies. Therefore, the severity of the infection is likely to be the major influence on the levels and the subsequent duration of detection of NSP antibodies.

An additional problem, not fully addressed by existing tests for NSP antibodies, is the detection of vaccinated animals which have contact with live FMD virus and become virus carriers. Because of the protection provided by the vaccine, there may only be limited

replication of the virus and very low levels of NSP expression and therefore antibody production by the infected animal, thus exceeding the sensitivity of the tests currently available. An NSP ELISA was not capable of detecting antibodies in all tested carrier animals when sera was examined for antibodies to NSPs L, 2C, 3A, 3D and 3ABC by an indirect ELISA profiling (Mackay et al., 1998).

A considerable variation was observed in the antibody response to NSPs of both naïve and vaccinated animals following infection. Animals that showed clinical signs but eliminated the virus are as likely to be sero-positive several months after infection as clinically affected animals which remain persistently infected. Therefore, the NSP tests should not be used on an individual basis but on a herd basis with an appropriate sampling schedule, which includes the younger population of animals born at the time when transmission was not expected to occur. It can confirm the absence of viral activity in the herd. NSP tests have been shown to be useful in detecting viral activity in naïve or vaccinated populations, but may not be a useful indicator of the current virological status of an individual animal. In herds vaccinated with potent FMD vaccines, some animals that are exposed to live virus will support replicating virus as vaccines do not induce full herd protection. Although these animals may not present any clinical signs, they will seroconvert to some NSPs. Therefore, testing the entire herd should detect previous viral activity and determine the potential for the presence of carrier animals (Clavijo et al., 2004[a]).

CHAPTER III

MATERIALS AND METHODS

In this study, the author divided the study into 2 phases. In phase I, the confirmation of FMDV type O was performed using RT-PCR, and in phase II, the 3ABC gene of FMDV type O was cloned into a bacterial expression vector and analyzed by DNA sequencing. The conceptual framework is shown in Figure 3.1

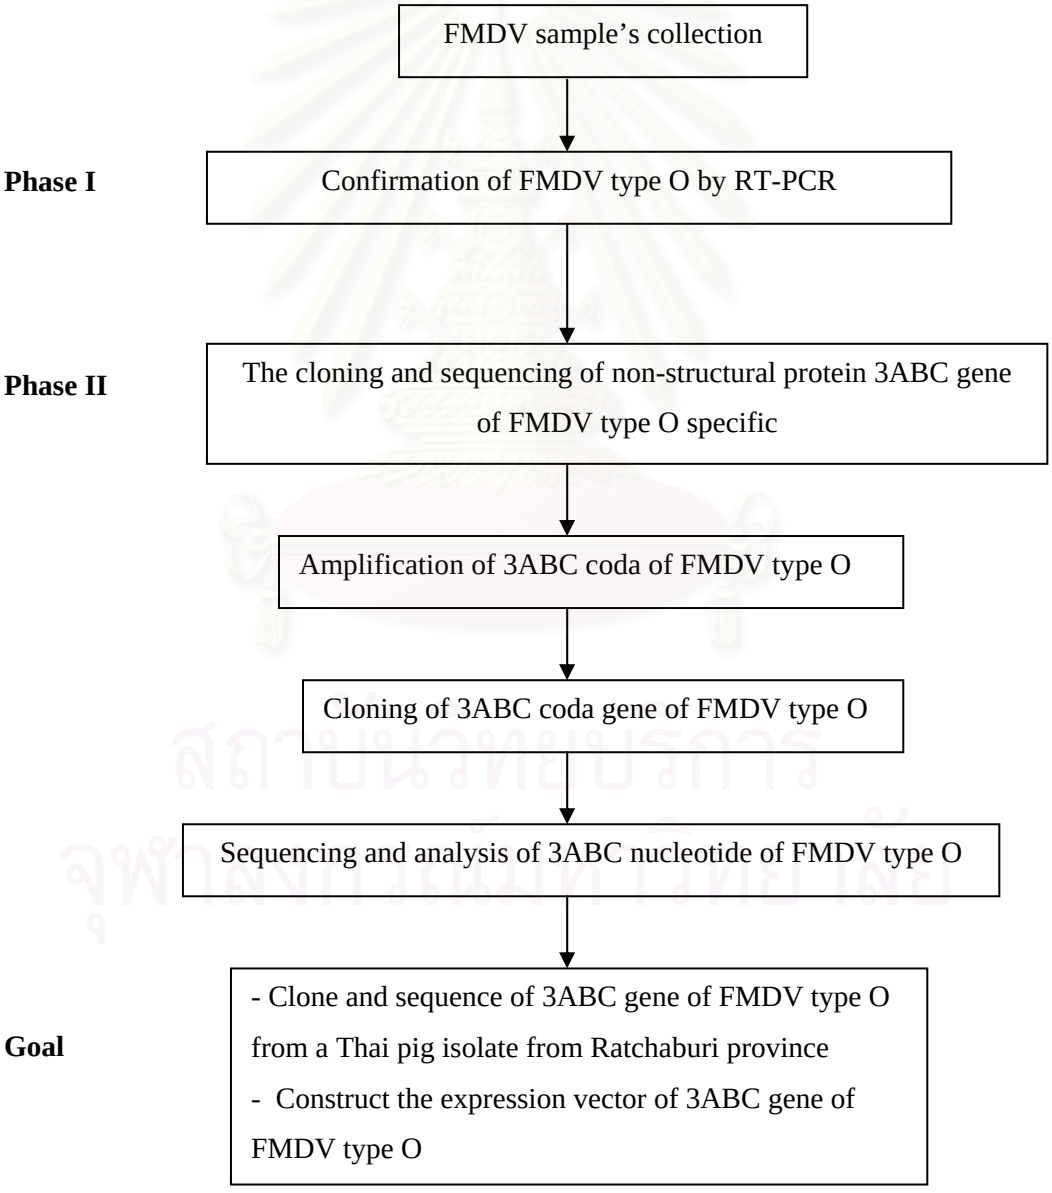

Figure 3.1 The conceptual framework in this study

FMDV sample's collection

A total of five FMDV outbreak's farms were selected in this study. The vesicular fluid and erosion tissue samples of FMDV infected pigs were collected in 10% glycerine buffer from pig farms. All FMDV samples were stored at -80 °C until further study.Those farms which reported the incidence of FMDV type O outbreak in 2005 were located in Nakhon pathom (1 sample), Phetchaburi (2 samples), and Ratchaburi province (2 samples) (Department of Livestock Development. 2005[b]). The FMDV stock from Ratchaburi province was selected to clone into a bacterial expression vector because the Ratchaburi province is the first province that officially reported incidence of FMD outbreak in 2005.

Phase I Confirmation of FMDV type O by RT-PCR

All of the farm pig samples were extracted for total viral RNA. The FMDV O-1C124 and 3ABC cDNA were synthesized. The PCR with type O specific primers were analyzed.

1. FMD viral RNA extraction

Total RNA of samples was isolated from farm pig samples and from killed vaccine (3 types; type O, A, and Asia1, DLD, Thailand) using Purelink® viral RNA/DNA mini kit under construction from manufacturer (Invitrogen, USA). The samples were added with 25 µl of Proteinase K and 200 µl of Lysis Buffer (containing 5.6 µg Carrier RNA), and slightly homogenized. The homogenate was incubated at 56 °C for 15 minutes. Consequentially, 250 µl of 95% ethanol was added and vigorously vortexing for 15 seconds. The mixture was incubated at room temperature for 5 minutes and centrifuged briefly to remove any drops from the inside of the lid. The lysate was transferred to the Viral Spin Column (Invitrogen, USA). Then, the pellet was collected by centrifugation at about 6,800 x g for a minute. The total RNA was dissolved with 20 µl of Sterile, RNase-free water and kelp at -80°C.

2. First-stranded cDNA synthesis

The first-stranded cDNA was generated using Omniscript Reverse Transcription kit under construction from manufacturer (Qiagen, Germany). Two micrograms of the total RNA sample was added into the mixture (20 µl of final volume) of 0.1 µM of oligo (dT) primers, 1x of buffer RT, 2 µl of the dNTP mix (5 mM of each dATP, dCTP, dGTP, and dTTP), 1µl of

reverse transcriptase (200 units/µl), 0.5 µl of recombinant RNasin® ribonuclease inhibitor (20U), and RNase-free water; respectively. The reaction was incubated at 37 °C for 1 hour and immediately incubated at 93 ºC for 5 minutes to terminate the reverse transcription activity. The cDNA was stored at -20 ºC until used.

3. Confirmation of FMDV type O (O-1C$_{124}$) by RT-PCR

The samples from infected farm pigs were separated into two parts. The first part was sent to confirm typing at Regional Reference Laboratory for Foot and Mouth disease in South East Asia (RRL), Nakhon Ratchasima, Thailand. The second part was confirmed of FMDV typing by using RT-PCR at Department of Veterinary Medicine, Chulalongkorn University, Bangkok Thailand.

The PCR reactions were contained 50 µl of the mixture as follwed: 5 µl of cDNA, 2x PCR buffer, 400 µM dNTPs, 7.5 mM $MgCl_2$, 20 pmole of each primer, and 1 U *pfu* DNA polymerase. PCR amplifications were conducted on a PCR T-gradient Thermoblock® (Biometra®, Germany). PCR thermocycing conditions were an initial denaturation at 94°C for 4 minutes, and 40 cycles of denaturation for 1 minute at 94°C, primer annealing for 1 minute at 50°C, and DNA extension for 90 seconds at 72°C and a final extention at 72°C for 5 minutes. PCR products were visualized on 2% agarose. The PCR products size of FMDV type O were approximately at the molecular weight of 1301 bp. Gel were purified using QIAQuick Gel Extraction kit (Qiagen, Germany). Representative DNA samples were submitted for sequencing at 1st base Inc. (Singapore). The primers used for confirmation of FMDV typing is listed in Table 3.1

Table 3.1 The O-1C_{124} primers used for confirmation of FMDV typing (Knowles and Samual, 1994)

Primer designation	Sequence (5'-3')	Amplicon size (bp)
O-1C_{124}-F	ACCAACCTCCTTGATGTGGCT	1301
O-1C_{124}-R (NK61)	GACATGTCCTCCTGCATCTG	

Phase II The cloning and sequencing of non-structural protein 3ABC gene of FMDV type O specific

The experiment in this phase included 1) amplification of 3ABC gene of FMDV type O by RT-PCR, 2) cloning of 3ABC cDNA and 3) sequencing and analysis of 3ABC nucleotide.

1. Amplification of 3ABC gene of FMDV by RT-PCR

The PCR product from the FMDV was used as template for PCR amplification of the 3ABC gene with a pair of degenerate oligonucleotide primers. The two primers were designed based on the 3ABC gene from FMDV type O strain Tibet/CHA/99 (Genbank accession number is AJ539138), which has the same similarity to the previous report from Genbank of 3ABC FMDV type O in Thailand. The cloning sites were incorporated into the forward and reverse primers. Their sequences were as follows: forward primer, 3ABC-F: 5' CACC CAA TTC CTT CCC AAA AGG CT 3' and reverse primer, 3ABC-R: 5' GTG GTG TGG TTC GGG GTC AA 3'. Locations on the corresponding genes of 2 primers designed in this study are shown in Appendix C.

The PCR reactions were contained 50 µl of the mixture as follwed: 2x PCR buffer, 400 µM dNTPs, 7.5 mM $MgCl_2$, 20 pmole of each primer, and 1 U *pfu* DNA polymerase. PCR amplifications were conducted on a PCR T-gradient Thermoblock® (Biometra®, Germany). PCR thermocycing conditions were an initial denaturation at 94°C for 4 minutes, and 40 cycles of denaturation for 1 minute at 94°C, primer annealing for 1 minute at 50°C, and DNA extension for 90 seconds at 72°C and a final extension at 72°C for 5 minutes. PCR

products were visualized on 2% agarose. The size of 3ABC gene of FMDV type O PCR product was approximately 1303 bp. Gel were purified using QIAQuick Gel Extraction kit (Qiagen, Germany).

2. Cloning of 3ABC cDNA into pET160/GW/D-TOPO vector

After gel extraction, the 3ABC gene was cloned into the pET160/GW/D-TOPO (His tag) vector (Invitrogen, USA), named as 3ABC recombinant plasmid. The 3ABC recombinant plasmid was transformed into an *E.coli* strain One Shot® TOP10 (Invitrogen, USA) using chemical transformation. The transformants were selected on the ampicillin LB agar plates. Then, the positive transformants were analyzed by using PCR. For PCR primers, use a combination of the T7 Promoter sequencing primer and 3ABC-R primer. The sizes of transformant PCR product was approximately 1524 bp in length, respectively. A single colony of *E. coli* harboring a 3ABC recombinant plasmid was picked up and grown in 1.5 ml LB broth containing 100 μg/ml of ampicillin and incubated with shaking at 37 ºC for an overnight. The recombinant plasmid was prepared by the QIAgen plasmid miniprep kit (Qiagen, Germany).

3. Sequencing and analysis of 3ABC nucleotide of FMDV type O

The single clone of transformant was analyzed for the nucleotide sequencing. The obtained sequence was compared with the previously reported 3ABC sequence's databases in Genbank as follow; O1Campos (Genbank accession number is AJ320488), Tibet/CHA/99 (Genbank accession number is AJ539138), O1manisa iso87 (Genbank accession number is AY593823), UK2001 iso84 (Genbank accession number is AY593836) and Taiwan97 iso106/112 (Genbank accession number is AY593835); respectively using Bioedit Sequence Alignment Editor (Hall, 1999) and the phylogenetic and molecular evolutionary analyses were conducted using MEGA version 4.1 (Tamura et al., 2007) software. The homological data was analyzed.

CHAPTER IV

RESULTS

1. Confirmation of FMDV type O (O-1C$_{124}$ cDNA) by using RT-PCR

The report from Regional Reference Laboratory for Foot and Mouth Disease in South East Asia (RRL) at Nakhon Ratchasima about the samples from the studied farms was positive for FMDV type O by using cell culture technique.

In addition, the author succeeded to extraction for total viral RNA, synthesized the FMDV cDNA, and amplified the O-1C$_{124}$ genes of the five samples from pig farms in Nakhon pathom, Phetchaburi, Ratchaburi provinces and the sample from killed FMDV vaccine.

The PCR amplification products for FMDV type O (O-1C$_{124}$ genes) was run on 2% agarose gel at 110 volts for 60 min. The product lengths for each sample were confirmed and shown at the molecular weight of 1301 bp (Figure 4.1).

2.2 Cloning of 3ABC cDNA into pET160/GW/D-TOPO vector

The 1303 bp PCR products from 3ABC gene cDNA FMDV type O from pig farm in Ratchaburi province were cut and purified from 2% agarose gel. The purified PCR product was ligated and transformed into *E. coli* strain One Shot®TOP10 (Invitrogen, USA). Ten single white colonies were picked up and the corrected insertion was confirmed by using PCR with specific primers for T7 promoter gene (forward primer) and 3ABC gene (reword primer). In this study, five out of ten colonies of transformants were successfully confirmed and named as pET160/GW/D-TOPO/3ABC-CUVetmed01–05. The expected product sizes for this confirmation were shown at the molecular weight of 1524 bp as shown in Figure 4.3. It was appeared suggested that the selected clone contained a 3ABC expression plasmid with 1303 bp of 3ABC gene insertion. In addition, the five corrected recombinant plasmids were further confirmed by sequencing.

2.3 Sequencing and analysis of 3ABC nucleotides

The details of five recombinant plasmids of pET160/GW/D-TOPO/3ABC-CUVetmed01 – 05 were successfully sequenced and shown in Table 4.1. The 3ABC nucleotides of five recombinant plasmids were shown similar pattern. The author selected the pET160/GW/D-TOPO/3ABC-CUVetmed01 to further compare with the previously reported 3ABC databases from Genbank as follow; FMDV O1Campos (Genbank accession number is AJ320488), FMDV O1manisa iso87 (Genbank accession number is AY593823), FMDV Taiwan97 iso106/112 (Genbank accession number is AY593835), FMDV Tibet/CHA/99 (Genbank accession number is AJ539138), and FMDV UK2001 iso84 (Genbank accession number is AY593836) by using Bioedit Sequence Alignment Editor (Hall, 1999) software as shown in Figure 4.4. The homology among the pET160/GW/D-TOPO/3ABC-CUvetmed001 and the previously reported 3ABC databases from Genbank were performed the phylogenic tree by using MEGA version 4.1 (Tamura et al., 2007) software (Figure 4.5). The percentage homology between the pET160/GW/D-TOPO/3ABC-CUvetmed001 recombinant plasmids and the previously reported 3ABC databases from Genbank was shown in Table 4.2. The results revealed high percent homology (more than 90%) within this 3ABC region with FMDV O1Campos (90.90 %), FMDV O1manisa iso87 (91.06 %), FMDV Tibet /CHA/99 (100 %) and FMDV UK2001 iso84 (98.93 %). However, the homological data with 3ABC gene of FMDV type O from Taiwan97 iso106/112 was only 82.89%.

The phylogenetic tree of the pET160/GW/D-TOPO/3ABC-CUVetmed01 was compared with the five previously reported 3ABC databases as showed in Figure 4.5. The results showed that the 3ABC gene of FMDV type O from infected pig in Ratchaburi province in 2005 belonged to a group with the FMDV Tibet /CHA/99 and the FMDV UK2001 iso84. However, the FMDV O1Campos, FMDV O1manisa iso87 and FMDV Taiwan97 iso106/112 were grouped apart from those.

Tibet/CHA/99	100.00	90.90	91.06	82.89		98.93
UK2001 iso84	98.93	90.51	90.67	82.81	98.93	

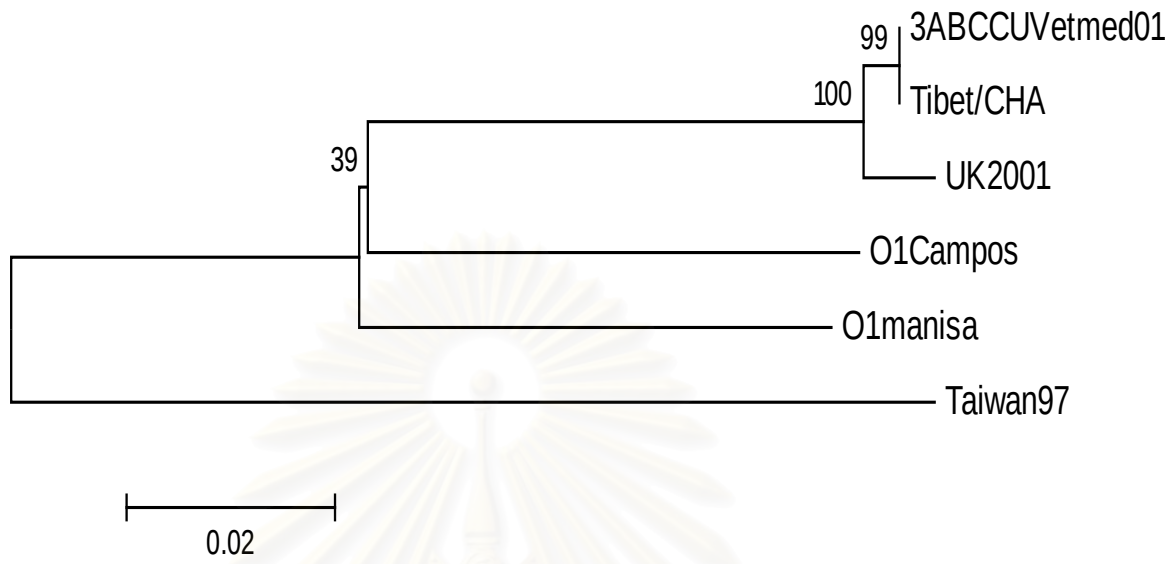

Figure 4.5 The phylogenetic tree of the pET160/GW/D-TOPO/3ABC-CUVetmed01 compared with the five previously reported 3ABC databases.

The tree was generated from nucleotide sequence of 3ABC gene using the neighbor-joining algorithm method. The length of horizontal branches reflects phylogenetic distance relationship. The vertical lines were non-informative and set for clearity only.

CHAPTER V

DISCUSSION

In this study, the author succeeded in the confirmation of FMDV type O from the field sample by using RT-PCR. It may become useful tools for the typing of FMDV type O from the field sample and investigation of FMD in Thailand.

The FMDV type O sample was selected from pig farm in Ratchaburi province. The reason for choosing this sample to amplify 3ABC cDNA and clone into pET160/GW/D-TOPO vector is the first province that officially reported incidence of FMD outbreak in 2005. Furthermore, the local FMDV sample should be more suitable to be an antigen for detection of antibody from FMDV infected pigs in Thailand because of the similarity of immune responses induced by a chosen FMDV sample and by infection from a field virus.

Pigs are important economic animals in Thailand and a vaccination program is usually implemented in Thai pig population with trivalent FMDV killed vaccine made in Thailand. Although, it is considered that vaccinated pigs should not become carriers after field infection, the assay based on antibody against NSP is still important for FMDV eradication program in pig population (Chung et al., 2002). Rodriguez et al. (1994) assessed the immunogenicity of different FMDV proteins in swine. After analyzing specificity of anti-FMDV antibodies produced against NSPs in sera from infected and vaccinated pigs, they concluded that the NSP 3ABC was the most immunogenic virus-induced polypeptide and would be used to distinguish between infected and vaccinated pigs. It was also shown that the NSP 3ABC antibodies were detectable from two weeks post-infection. Other studies have shown that infected animals can be clearly differentiated from vaccinated animals by the presence of antibodies to 2C, 3A and 3ABC induced by viral replication following infection (Mackay et al., 1998). There is considerable variation in the magnitude of the overall response to NSPs in individual animals to each of NSPs examined, which in turn reflected the different extent of viral replication. Therefore, the amount of NSP to which animal was exposed and the difference in the immunogenicity of the different NSPs was observed. However, it was concluded that the NSPs 3ABC was the most reliable single indicator of infection in both bovine and porcine sera (Mackay et al., 1998). The immune response to 3ABC appeared early after infection and antibody to 3ABC could be detected for longer than antibody to other

NSP. Clavijo et al. (2004[b]) studied the detection level of antibody responses to NSPs in animals infected with different serotypes of FMDV. They did not find any variation in the detection.

In this study, RT-PCR was successful for confirmation of FMDV type O and amplification of 3ABC gene cDNA of FMDV type O. Following RT-PCR technique, some mutation may occur due to the lack of error repairing systems in the reverse transcriptase as mentioned before. It has also been suggested that the reverse transcriptase can be responsible for mutations but Cottam et al. (2009) reported no significantly difference between the proof reading reverse transcriptase and no-proof reading reverse transcriptase. However, other conditions should be varied to reduce errors. The oligonucletide primers are the one factor to be concerned and the primer concentration is also importance. The high primer concentration may lead to misprint and accumulation of non-specific PCR products. Generally, five pmol of each primer is an optimal concentration; therefore each primer should be optimized (Kawasaki et al., 1990). In this study, RT-PCR was run following the Access-RT-PCR protocol. However, the concentration of the primers was optimized at twenty pmol which are the lowest effective concentration and the lowest amount of primer dimers.

RT-PCR using total RNA from FMDV type O infected pig in Ratchaburi resulted in band of 1303 bp, corresponding to the complete 3ABC coding sequence excluding 3 and 4 bases at the 5' and 3' ends, respectively. These nucleotide bases were removed to avoid proteolytic cleavage of the 2B-3A junction by the 3C protease. Clavijo et al. (2004[b]) reported protein expression experiments and indicated that if the sense primer included the 3' end coding sequences of the 2B protein, the 3ABC protein was expressed but 6xHis tag would not be detected by western blotting probably due to a proteolytic cleavage of this 6xHis tag.

The 3ABC cDNA from FMDV infected pig in Ratchaburi province in 2005 was cloned into pET160/GW/D-TOPO vector. There are factors concerning in selecting the cloning and expression systems. There were largely depends on the biochemical and biological properties of interested proteins, the requirement of an amount of recombinant proteins, as well as the nature of the experiments (Geisse et al., 1996). The 3ABC cDNA of FMDV was successfully cloned and expressed in many systems and expressed proteins had immunogenicity to react with anti-3ABC antibodies from FMDV infected pigs. In this study, *E. coli* cloning and expression system were selected because this system was cheap, fast and easy to manipulate. Other reports had preferred to produce the 3ABC protein in baculovirus to avoid many problems such as the production of recombinant proteins in an insoluble form or

inclusion body (Silberstein et al., 1997). In addition, the possibility of having false positives due to the presence of anti *E.coli* antibodies. However, recombinant proteins produced from baculovirus was more expensive, required cell culture facilities and usually resulted in a lower yield than *E.coli* derived recombinant proteins (Clavijo et al., 2004[b]).

The plasmid pET160/GW/D-TOPO provides high ligation efficiency due to the attached topoisomerase at both ends of this linear plasmid. The directional ligation of blunt end PCR product saves time for confirming gene orientation, so it needed only PCR technique to determine the inserted gene. In addition, the Gateway® Technology is a universal cloning method that takes advantage of the site-specific recombination properties of bacteriophage lambda to provide a rapid and highly efficient way to move interested gene into multiple vector systems (Invitrogen, 2004). This system can provide alternative method to transfer the 3ABC gene of FMDV type O to the other expression vectors such as yeast, baculovirus and mammalian system.

Generally, NSPs are crucial roles for viral propagation and are more conserved region than the structural proteins (Feng et al., 2004). The mutations or deletions in the NSPs could be detrimental to viral replication and protein processing (van Rensburg et al., 2002). The VP4, VP2, VP3, 2A, 2B, 2C, 3B, 3C and 3D nucleotides were more conserved among and within the different FMDV strains. The 3A nucleotide exhibited the lowest conservation similarity among Cathay topotype and PanAsia strains of FMDV type O (Zhao et al., 2008). But 3A nucleotide of the FMDV type A Indian isolates was also conserved (Mohapatra et al., 2009).

In this study, the 3ABC of FMDV type O was completely sequenced and reported for the first time. The homology and the generation of phylogenetic tree of this gene in FMDV type O were analyzed. The sequence showed at 82 – 100% homology of 3ABC nucleotides with other previously reports from Genbank databases. This result indicated that 3ABC gene of FMDV type O is the conserved gene and correlated with study from Sun et al. (2004) which showed that the 3ABC nucleotide and amino acid sequences among different strains of FMDV were similar. From sequential analysis, pET160/GW/D-TOPO/3ABC-CUVetmed01 showed 100% similarity at nucleotide level with Tibet/CHA/99 strain. Furthermore, pET160/GW/D-TOPO/3ABC-CUVetmed01 was strongly clustered with UK2001 iso84, suggesting a relatively recent common ancestor for these isolates. Although this virus causing outbreak in Ratchaburi was genetically and most closely related to that causing an outbreak of type O in Tibet, it is not clear and no evidence that viruses were transmitted between Thailand

and Tibet. However, FMDV genome region coding for other regions such as outer-capsid polypeptide, VP1 sequences are necessary to further study and useful for determining the prevalence of intratypic recombination in the filed.

Taken together, the system developed in this study may become useful tools for further improvements of technique for expression of recombinant 3ABC proteins. It will develop specific recombinant proteins for detection antibody to FMDV infected pigs in Thailand. This study also provides a preliminary 3ABC sequence's data of FMDV type O in a Thai pig and allows us to understand more on genotype of FMDV by genetic characterization.

Conclusion

This report represented study of molecular biology of 3ABC gene of FMDV type O in Ratchaburi province in 2005. The confirmation of FMDV type O (O-1C_{124} cDNA) using RT-PCR technique may be beneficial for a monitoring and a diagnostic tool in typing confirmation of FMDV type O in swine herds where epizootic viruses are concerned. Moreover, the author described the cloning, sequencing and construction of plasmid 3ABC gene DNA expression vector in this thesis. The obtained knowledge and tools in this study contributes to not only on the basic research of 3ABC nucleotides of FMDV type O but also on the applied researches for improved diagnostic tools to detect FMDV infection in pig.

From this study, suggestions for further studies are FMDV 3ABC recombinant protein expression, purification and reactivity of this recombinant protein.

APPENDICES

APPENDIX A

Instruments and chemical substances

1. A -20°C refrigerator, Model SF-C997 (Sanyo, Thailand)
2. A -80°C refrigerator, Model 905 (Thermofisher Scientific, USA.)
3. Centrifuge and Microcentrifuge
4. Experimental glasswares
5. Gel document system, Model GVM 20 (Synoptics, UK.)
6. Gel electrophoresis system, Model GE-100 (Bioer technology co. Ltd., China)
7. Heat block (Labnet International Inc., USA)
8. Incubator, Model BE-400 (Memmert Inc., Germany)
9. Lamina air flow, Model Bio II A (Telstar, Spain)
10. Micropipette (Labnet, USA.) and Micropipette tips
11. PCR assay
    - 11.1 Agarose gel (Molecular grade)
    - 11.2 100 bp plus DNA marker (Generuler™, Fermentus, Canada)
    - 11.3 1 kbp DNA marker (Promega, USA)
    - 11.4 Ethidium Bromide 10 mg/ml (Sigma Aldrich Inc®, USA)
    - 11.5 Gel electrophoresis buffer (TAE)
    - 11.6 Loading dye (Fermentus®, Canada)
    - 11.7 *pfu* DNA polymerase and mixture (Fermentus®, Canada)
12. PCR cabinet (Biometra®, Germany)
13. PCR tubes and Microcentrifuge tube 1.5 ml
14. Vortex, Model K 550-GE (Scientific Inc., USA.)
15. Shaking Incubator, Model 311DS (Labnet International Inc., USA.)

APPENDIX B

Reagents and preparations

Reagents for agarose gel electrophoresis

1. 10 mg/ml Ethidium bromide

- Ethidium bromide	1	g
- Distilled deionized water	1,000	ml

Add 1 g of ethidium bromide to 100 ml of distilled deionized water. Stir on a magnetic stirrer for several hours to ensure that the dye has dissolved. Wrap container in aluminum foil or transfer to a dark bottle and store at room temperature.

2. 50X TAE (Tris-Acetate buffer) 1000 ml contains

- Tris base	242.0	g
- Glacial acetic acid	57.1	ml
- 0.5 M EDTA pH 8.0	100.0	ml
- Distilled deionized water	1,000	ml

Add 242 g of Tris base, 57.1 ml of Glacial acetic acid and 100 ml of 0.5 M EDTA pH 8.0 to 500 ml of distilled deionized water and then adjusts the final volume to 1,000 ml. Sterilize the solution by autoclaving.

3. 0.5 M EDTA, pH 8.0 1000 ml contains

- Disodium ethylene diamine tetraacetate. $2H_2O$	186.1	g
- Distilled deionized water	800.0	ml

Add 186.1 g of disodium ethylene diamine tetraacetate. $2H_2O$ to 800 ml of distilled deionized water. Stir vigorously on a magnetic stirrer. Adjust the pH to 8.0 with NaOH. Dispense into aliquots and sterilize by autoclaving. The disodium salt of EDTA will not go into solution until the pH of the solution is adjusted to 8.0 by the addition of NaOH.

4. 1 M Tris HCl, pH 8.0 1000 ml contains

- Tris (ultrapure)	121.1	g
- Distilled deionized water	800.0	ml

Dissolve 121.1 g of Tris in 800 ml of distilled deionized water. Adjust the pH to 8.0 by adding conc. HCL 42.0 ml and then adjust the final volume to 1,000 ml. Sterilize the solution by autoclaving and store the solution at room temperature.

APPENDIX C

Locations of primers on the corresponding genes designed in this study

O-1C$_{124}$-F and O-1C$_{124}$-R (NK61) primers

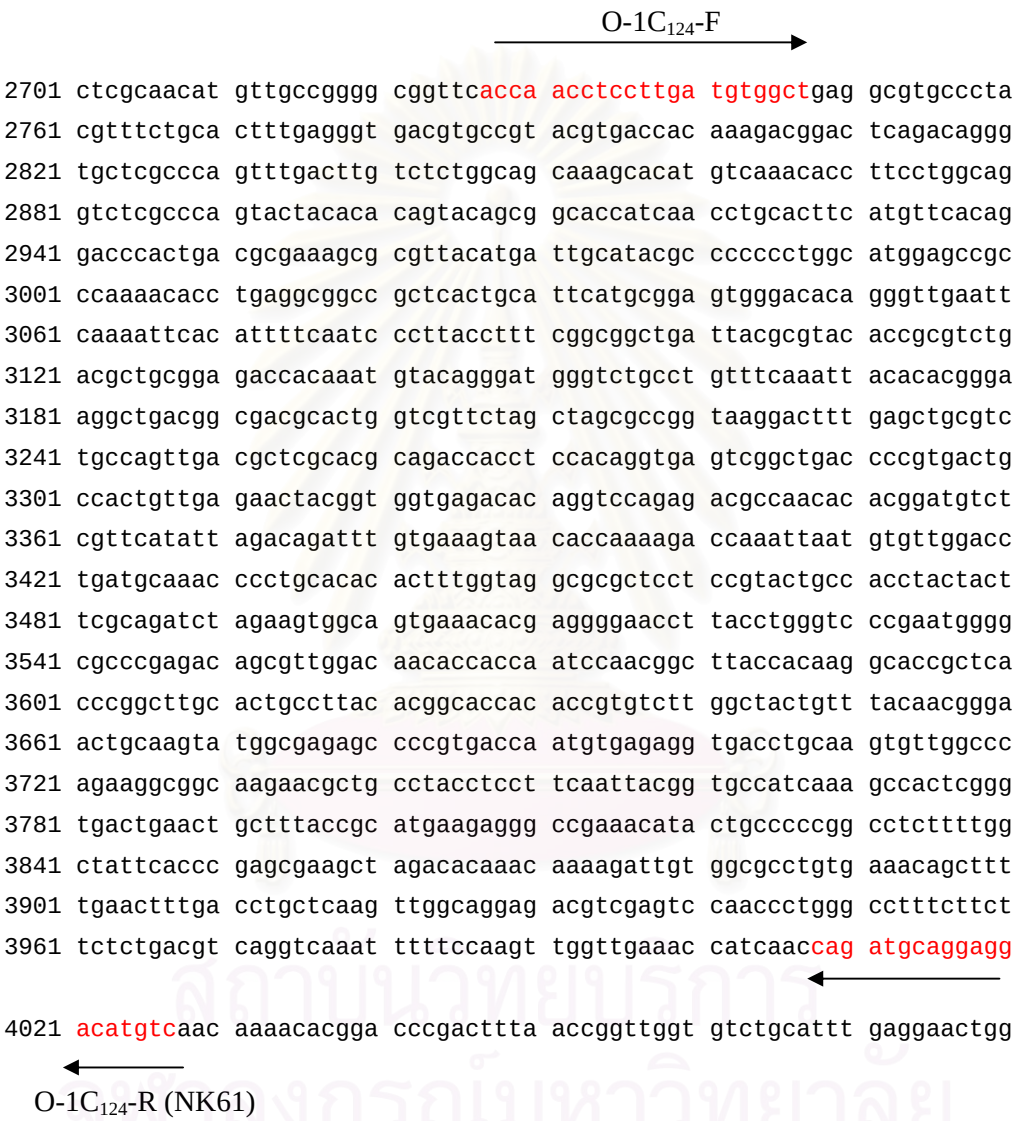

Figure A. Locations and nucleotide sequence of O-1C$_{124}$-F and O-1C$_{124}$-R (NK61) primers on VP3 – 2B gene of FMDV type O isolate Tibet /CHA/99 (Genbank accession number AJ539138). The arrows indicated position and direction of primers.

3ABC-F and 3ABC-R primers

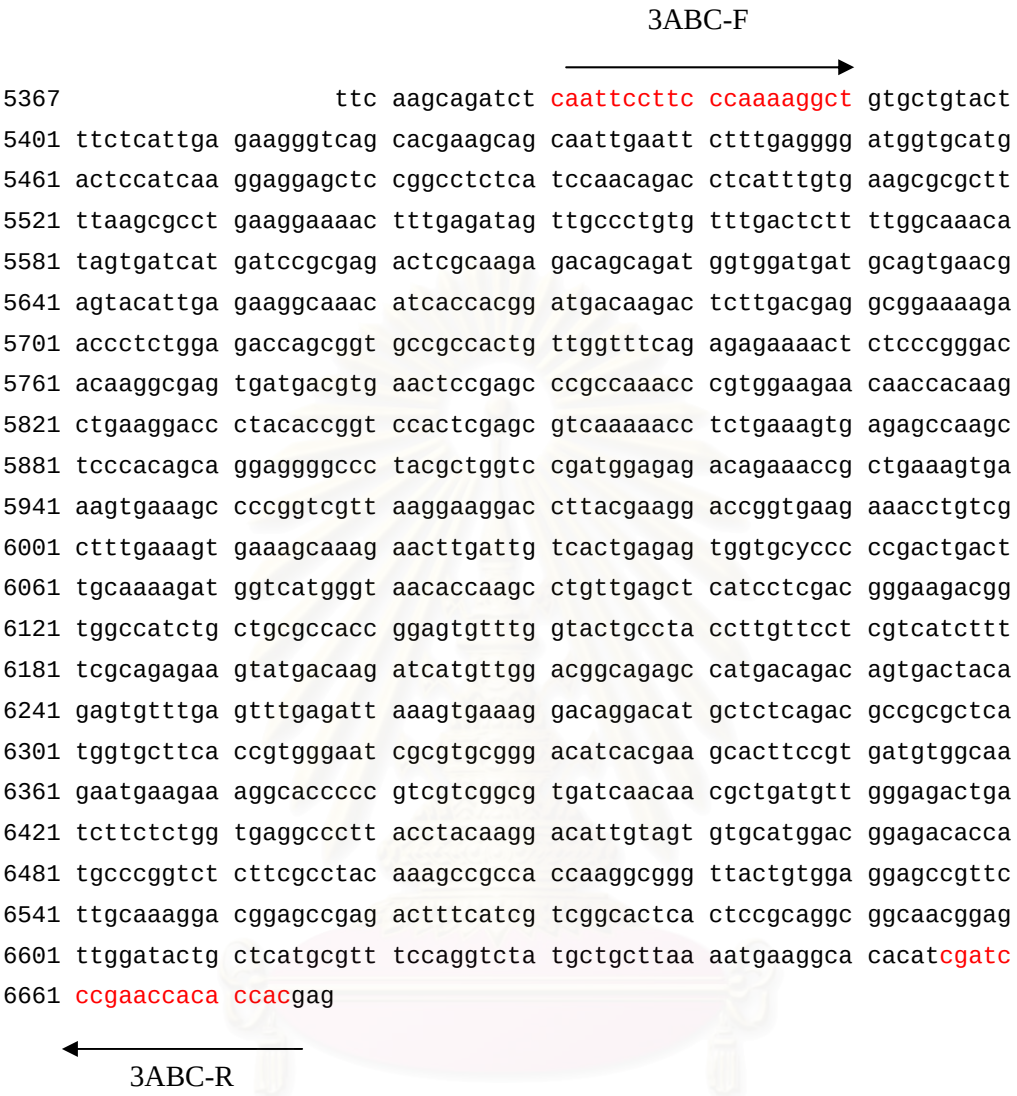

Figure B. Locations and nucleotide sequence of 3ABC-F and 3ABC-R primers on 3ABC gene of FMDV type O isolate Tibet /CHA/99 (Genbank accession number AJ539138). The arrows indicated position and direction of primers.

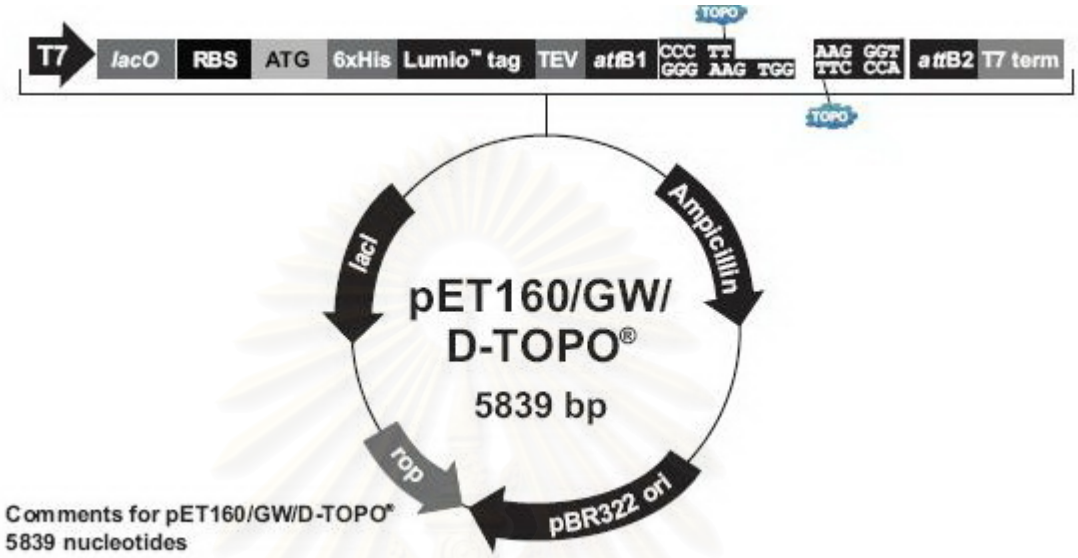
APPENDIX D

Physical map of plasmid pET160/GW/D-TOPO



Comments for pET160/GW/D-TOPO®
5839 nucleotides

T7 promoter/priming site: bases 21-40
lac operator (lacO): bases 40-64
Ribosome binding site (RBS): bases 94-101
Initiation ATG: bases 109-111
Polyhistidine (6xHis) region: bases 112-129
Lumio™ tag: bases 142-159
TEV recognition site: bases 169-189
*att*B1 site: bases 196-220
TOPO® recognition site1: bases 232-236
Overhang sequence (c): bases 237-240
TOPO® recognition site 2: bases 241-245
*att*B2 site: bases 257-281
T7 transcription termination region: bases 307-435
T7 reverse priming site: bases 346-365
bla promoter: bases 740-838
Ampicillin (*bla*) resistance gene: bases 839-1699
pBR322 origin: bases 1844-2517
ROP ORF (c): bases 2888-3079
lacI ORF (c): bases 4391-5482

(c) = complementary strand

BIOGRAPHY

Miss Kulisara Marupanthorn was born on September 1, 1981 in Ayutthaya, Thailand. She graduated from the Faculty of Veterinary Science, Chulalongkorn University, Thailand in 2005. After that, she worked as a instructor at Rajamangala University of Technology Tawan-ok. She enrolled the degree of Master of Science in the Department of Veterinary Medicine, Faculty of Veterinary Science, Chulalongkorn University in 2006.
