PARKPHUM ORACHORN: DEVELOPMENT OF TECHNIQUE FOR SCREENING LIQUIDS IN UNOPENED BOTTLE USING LOW ENERGY X-RAY TRANSMISSION. ADVISOR: ASSOC. PROF. NARES CHANKOW, CO-ADVISOR: ASSOC. PROF. SOMYOT SRISATIT, pp.

Since August 2006 after the discovery of terrorists' attempts to explode airplanes with liquid explosives in United Kingdom, each airline passenger is allowed to carry only a maximum of 100 ml liquid in each container and a total of not more than 1,000 ml in carry-on luggage. This measure was adopted to prevent bringing sufficient amount of fuel oil, alcohol, hydrogen peroxide or other flammable and explosive liquids into the aircraft. In this research, X-ray transmission technique was experimentally investigated using low energy X-rays between 13.6 – 43.5 keV emitted from  $^{238}\text{Pu}$  radioisotopic source and linear attenuation coefficient of liquids were calculated. The results indicated that the technique could clearly distinguish water, alcohol and fuel oil while its sensitivity is dependent upon radiation energy and diameter of the bottle. Other kinds of liquid are also tested. For bottles or containers having various diameters, multi-energy X-rays may be more practical. This technique is possible to employ the technique for screening bottled liquids contained in unopened bottles at airports.

## ACKNOWLEDGEMENTS

I would like to thank my advisor Assoc.Prof.Nares Chankow and Assoc.Prof.Somyot Srisatit for their patience and support in my dissertation.

Thanks are also extended to Development and Promotion of Science and Technology Talents Project (DPST) for a scholarship.

I am also grateful to Mr. Chalermpong Polee , Mr. Pongyuth Sriploy for their valuable assistance during experiments.

I would like to thank my family and my Ph.D.-student friends for their encouragement and kindness.

## CHAPTER I

### INTRODUCTION

#### 1.1.Introduction

In 2006, the terrorist attempts to blow up several aircraft during flight using liquid explosives at London-Heathrow Airport, the European Commission created the rules on aviation security to fix the problem and prevent malicious threats.<sup>(1)</sup>

These rules restrict passengers on carrying liquids, aerosols and gels (LAGs)<sup>(2)</sup> past screening points, the restrictions are as follows:

- Liquids in individual containers with volumes of not more than 100 ml packed in one transparent 1 litre re-sealable plastic bag as show in figure 1.1.

Figure 1.1 Liquids capacity and re-sealable plastic bag.

- Liquids which are to be used during the trip for medical purposes or special dietary requirements, including baby food.
- Duty free liquids must be packed in transparent plastic bag, which proof of purchase at airside at that airport on that day is displayed.

These rules may change in the future with the suitable technology for screening in liquid explosive.

For most convenience and safety, reliable methods and devices are needed to identify liquid in unopened bottles. Several methods have been introduced and tested such as vapor and trace detection, x-ray imaging<sup>(3)</sup>, x-ray computed tomography (CT)<sup>(4)</sup>, neutron techniques, nuclear magnetic resonance (NMR)<sup>(5)</sup>, magnetic resonance imaging (MRI) and Raman spectroscopy<sup>(6) (7)</sup>. Each method has advantages and limitations.<sup>(8)</sup>

This research introduces a simple low energy x-ray and gamma-ray transmission technique to identify liquid types in unopened bottles. Low energy x-rays and gamma-rays in the range of approximately 10 to 120 keV emitted from radioisotope sources are experimentally investigated including  $^{57}\text{Co}$ ,  $^{238}\text{Pu}$  and  $^{241}\text{Am}$ . The transmitted intensity is measured with a compact and good resolution CdTe detector. The transmission factors of liquids contained in bottles of different sizes and thicknesses are investigated which are dependent upon liquid composition, diameter of bottle and photon energy.

## 1.2.Objective of Research

1.2.1 To develop a method to screen the liquids in an unopened bottle by using the low energy x-ray transmission.

## 1.3.Scope of the Research

1.3.1 Investigate the factors affecting the effectiveness of the x-ray transmission technique in screening the liquids such as the X-ray energy, the diameter, thickness and material of the bottle.

1.3.2 Liquids to be investigated are such as nitro-explosives, peroxides, flammables and water-based solutions.

1.3.3 Design prototype equipment to be used for screening of liquid in bottle at airports.

#### 1.4. Research Methodology

Figure 1.2 Experiment set-up.

#### Material

- Low energy x-ray / gamma-ray source
- CdTe detector
- PREAMP & Powersupply
- Collimator
- Bottles and Liquids
- Computer for analysis

Passengers may carry liquid in bottles with difference in sizes ranging from a few centimeters up to about 10 centimeters in diameter. In principle, lower energy should give better sensitivity but will have lesser penetrating power. To cover wide range of bottle size in screening at airport, multi-energy x-ray/gamma-ray is needed. Radioactive sources with activities in the range of 1-100 mCi (37 MBq – 3.7 GBq) are tested for this purpose including  $^{57}\text{Co}$ ,  $^{109}\text{Cd}$ ,  $^{238}\text{Pu}$  and  $^{241}\text{Am}$ . X- and gamma-rays are detected with a compact CdTe detector for good energy resolution but does not require cooling with liquid nitrogen. The source and the detector are positioned on the opposite side of the bottle under inspection to obtain transmitted x- and gamma-ray intensities.

Transmission factors for several kinds of liquids contained in bottles having diameters ranging from 2.26 to 8.75 cm are first investigated by using 13.6 - 20.1 keV U L x-rays from  $^{238}\text{Pu}$  as well as 59.6 keV gammas from  $^{241}\text{Am}$  source and 122 keV gammas from  $^{57}\text{Co}$ . The ratio of transmitted intensities of ethyl alcohol, gasoline, and liquid explosive will compare with water ( $I_{XL}/I_{XW}$ ). The attenuation coefficient will be calculated to identify liquid types.

### 1.5.Expected Benefits

The developed technique to screen the liquids in an unopened bottle by using the low energy x-ray transmission can be used for carry-on baggage inspection.

## CHAPTER II

### THEORY

#### 2.1 Literature review

During the recent years, many techniques in explosive detection in the baggage were studied (K. Wells, D. Bradley: 2012)<sup>(9)</sup>. Such as x-ray scatter tomography by G. Harding (2004)<sup>(4)</sup> or x-ray transmission imaging(Q. Gong, R.I. Stoianb, D. S. Coccarellia, J. A. Greenberga, E. Verac, M.E. Gehma: 2018)<sup>(3)</sup> but some explosive is liquids so it is hard to detect liquid explosive in an unopened bottle. Triacetone triperoxide (TATP) is one of the most dangerous liquid explosives because of it very sensitive to impact, flame or electric discharge (R. Matyas, J. Chylkova: 2013)<sup>(10)</sup>. C. Eliasson, N.A. Macleod, and P. Matousek (2007)<sup>(6)</sup> use Raman technique to inspect H<sub>2</sub>O<sub>2</sub> 30% that is liquid explosive mixture and Raman technique can inspect it. But H<sub>2</sub>O<sub>2</sub> concentration for make TATP can be lower or higher(J.C. Oxley)<sup>(11)</sup>.

The linear attenuation coefficient is a parameter that can identify material types by using Lambert's Law equation. S.M. Dongarge and S.R. Mitkar (2012)<sup>(12)</sup> determined a linear attenuation coefficient of alcohol and other solution but the value had a small difference because of they used x-ray energy 360 keV. S.M. Midgley (2004)<sup>(13)</sup> measured linear attenuation coefficient by using low x-ray energy in a range of 30-140 keV and the results give more different value from each material.

The aim of this work was to obtain the technique that can classify liquid explosive and other hazardous liquids including with flammable liquid and liquid explosive mixture by using low energy x-ray transmission.

## 2.2 Attenuation coefficient

The principle of the x-ray and gamma-ray transmission technique has been well understood i.e. the transmitted intensity ( $I_x$ ) decreases exponentially with attenuation coefficient ( $\mu$ ) and thickness ( $x$ ) of material according to Lambert's law. The attenuation coefficient decreases as x- or gamma-ray energy increases except at the absorption edge energy.

Figure 2.1 Parameters in Lambert's law calculation.

$$I = I_0 e^{-\mu x} \quad (2.1)$$

Where  $I_0$  is intensity when there is no liquid in the bottle,  $I_x$  is transmitted intensity through liquid,  $x$  is thickness of liquid and  $\mu$  is linear attenuation coefficient of liquid. For mixture, the attenuation coefficient can be simply calculated from equation 2

$$\left(\frac{\mu}{\rho}\right)_{mix} = w_1 \left(\frac{\mu}{\rho}\right)_1 + w_2 \left(\frac{\mu}{\rho}\right)_2 + w_3 \left(\frac{\mu}{\rho}\right)_3 + \dots \quad (2.2)$$

Where  $\rho$  is physical density,  $\left(\frac{\mu}{\rho}\right)_{mix}$  is mass attenuation coefficient of mixture;  $\left(\frac{\mu}{\rho}\right)_1$ ,  $\left(\frac{\mu}{\rho}\right)_2$ ,  $\left(\frac{\mu}{\rho}\right)_3$  are mass attenuation coefficients of components number 1, 2 and 3; and  $w_1$ ,  $w_2$ ,  $w_3$  are weight fractions of components number 1, 2, and 3 respectively<sup>(12, 14)</sup>.

Theoretically, differences in the attenuation coefficients become larger at low energy, transmission of x- or gamma-ray may be applicable to inspect liquid types in

a bottle containing light elements such as water, alcohol, oil as well as other flammable and explosive liquids.<sup>(13)</sup>

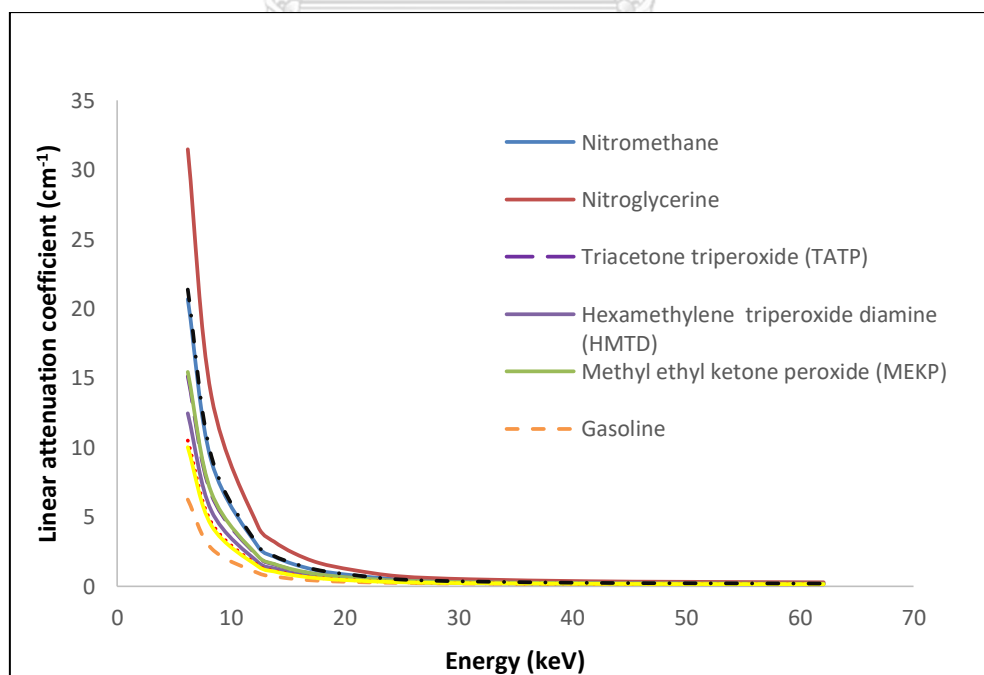

Figure 2. 2 Linear attenuation of hazardous liquids.

## 2.4 The Fundamental Law of Gamma-Ray Attenuation<sup>(15)</sup>

Figure 2.3 demonstrates a simple attenuation experiment. When gamma radiation of intensity  $I_0$  is incident on an absorber of thickness  $L$ , the transmitted intensity ( $I$ ) transmitted by the absorber is given by the equation.

$$I = I_0 e^{-\mu_l L} \quad (2.3)$$

Figure 2.3 The fundamental law of gamma-ray attenuation.<sup>(15)</sup>

Where  $\mu_l$  is the linear attenuation coefficient (expressed in  $\text{cm}^{-1}$ ). The gamma-ray transmission can be obtained from the ratio of  $I/I_0$ . Figure 2.4 shows exponential attenuation for three different gamma-ray energies and the transmission increases with increasing gamma-ray energy and decreases with increasing absorber thickness. Measurements with different sources and absorbers show that the attenuation coefficient  $\mu_l$  depends on the gamma-ray energy and the atomic number ( $Z$ ) and density ( $\rho$ ) of the absorber. For example, lead has a high density and atomic number and transmits a much lower fraction of incident gamma radiation than does a similar thickness of aluminum or steel. The attenuation coefficient in Equation 2.3 is called the linear attenuation coefficient. Figure 2.5 shows the linear attenuation of solid sodium iodide, a common material used in gamma-ray detectors.

Figure 2.4 Transmission of gamma rays through lead absorbers. <sup>(15)</sup>

Alpha and beta particles have a well-defined range or stopping distance; however, as Figure 2.4 shows, gamma rays do not have a unique range. The reciprocal of the attenuation coefficient  $1/\mu_i$  has units of length and is often called the mean free path. The mean free path is the average distance a gamma ray travels in the absorber before interacting.

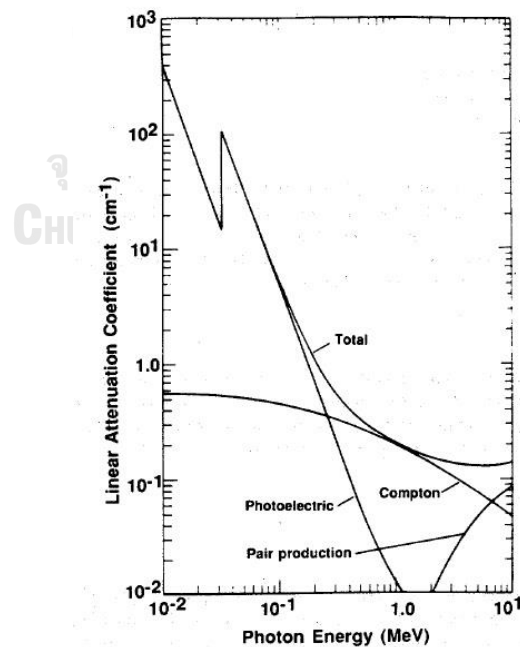

Figure 2.5 Linear attenuation coefficient of NaI showing contributions from photoelectric absorption, Compton scattering and pair production. <sup>(15)</sup>

### 2.4.1 Mass attenuation coefficient

The linear attenuation coefficient is the simplest absorption coefficient to measure experimentally, but it is not usually tabulated because of its dependence on the density of the absorbing material. For example, at a given energy, the linear attenuation coefficients of water, ice, and steam are all different, even though the same material is involved.

Gamma rays interact primarily with atomic electrons; therefore, the attenuation coefficient must be proportional to the electron density  $\rho$ , which is proportional to the bulk density of the absorbing material. However, for a given material the ratio of the electron density to the bulk density is a constant,  $Z/A$ , independent of bulk density. The ratio  $Z/A$  is nearly constant for all except the heaviest elements and hydrogen.

$$\rho = \frac{Z\rho}{A} \quad 2.4)$$

where  $\rho$  = electron density

$Z$  = atomic number

$\rho$  = mass density

$A$  = atomic mass

The ratio of the linear attenuation coefficient to the density ( $\mu/\rho$ ) is called the mass attenuation coefficient  $\mu$  and has the dimensions of area per unit mass ( $\text{cm}^2/\text{g}$ ). The units of this coefficient hint that one may think of it as the effective cross-sectional area of electrons per unit mass of absorber. The mass attenuation coefficient can be written in terms of a reaction cross section,  $\sigma$  ( $\text{cm}^2$ ):

$$\mu = \frac{N_0\sigma}{A} \quad 2.5)$$

Where  $N_0$  is Avogadro's number ( $6.02 \times 10^{23}$ ) and  $A$  is the atomic weight of the absorber. The cross section is the probability of a gamma ray interacting with a single atom. Using the mass attenuation coefficient, Equation 2.3 can be rewritten as;

$$I = I_0 e^{-\mu \rho L} = I_0 e^{-\mu x} \quad 2.6)$$

Where  $x = \rho L$

The mass attenuation coefficient is independent of density for the example mentioned above; water, ice, and steam all have the same value of  $\rho$ . This coefficient is more commonly tabulated than the linear attenuation coefficient because it quantifies the gamma-ray interaction probability of an individual element. The mass attenuation coefficient for compound materials can be calculated by the equation.

$$\mu = \sum \mu_i W_i \quad 2.7)$$

Where  $\mu_i$  = mass attenuation of the  $i^{\text{th}}$  element.

$W_i$  = weight fraction of the  $i^{\text{th}}$  element.

Interaction process

The gamma rays of interest to NDA applications fall in the range 10 to 2000 keV and interact with detectors and absorbers by three major processes: photoelectric absorption, Compton scattering, and pair production. In the photoelectric absorption process, the gamma ray loses all of its energy in one interaction. The probability for this process depends very strongly on gamma-ray energy  $E_\gamma$  and atomic number  $Z$ . In Compton scattering, the gamma ray loses only part of its energy in one interaction. The probability for this process is weakly dependent on  $E$  and  $Z$ . The gamma ray can lose all of its energy in one pair-production interaction. However, this process is relatively unimportant for fissile material assay since it has a threshold above 1 MeV.

### 2.4.2 Photoelectric absorption

A gamma ray may interact with a bound atomic, electron in such a way that it loses all of its energy and ceases to exist as a gamma ray. Some of the gamma-ray energy is used to overcome the electron binding energy, and most of the remainder is transferred to the freed electron as kinetic energy. A very small amount of recoil energy remains with the atom to conserve momentum. This is called photoelectric absorption because it is the gamma-ray analog of the process discovered by Hertz in 1887 whereby photons of visible light liberate electrons from a metal surface. Photoelectric absorption is important for gamma-ray detection because the gamma ray gives up all its energy, and the resulting pulse falls in the full-energy peak.

Figure 2.6 A schematic representation of the photoelectric absorption process. <sup>(15)</sup>

The probability of photoelectric absorption depends on the gamma-ray energy, the electron binding energy, and the atomic number of the atom. The probability is greater the more tightly bound the electron therefore, K electrons are most affected (over 80% of the interactions involve K electrons), provided the gamma-ray energy exceeds the K-electron binding energy. The probability is given approximately by Equation 2.8, which shows that the interaction is more important for heavy atoms like lead and uranium and low-energy gamma rays:

$$\tau \propto Z^4/E^3 \quad (2.8)$$

Where  $\tau$  = photoelectric, mass attenuation coefficient.

This proportionality is only approximate because the exponent of  $Z$  varies in the range 4.0 to 4.8. As the gamma-ray energy decreases, the probability of photoelectric absorption increases rapidly (see Figure 7). Photoelectric absorption is the predominant interaction for low-energy gamma rays, X-rays, and bremsstrahlung. The energy of the photoelectron  $E_e$  released by the interaction is the difference between the gamma-ray energy  $E_\gamma$  and the electron binding energy  $E_b$ :

$$E_e = E_\gamma - E_b \quad (2.9)$$

In most detectors, the photoelectron is stopped quickly in the active volume of the detector, which emits a small output pulse whose amplitude is proportional to the energy deposited by the photoelectron. The electron binding energy is not lost but appears as characteristic X-rays emitted in coincidence with the photoelectron. In most cases, these X-rays are absorbed in the detector in coincidence with the photoelectron and the resulting output pulse is proportional to the total energy of the incident gamma ray. For low-energy gamma rays in very small detectors, a sufficient number of K X-rays can escape from the detector to cause escape peaks in the observed spectrum; the peaks appear below the full-energy peak by an amount equal to the energy of the X-ray.

Figure 2.7 shows the photoelectric mass attenuation coefficient of lead. The interaction probability increases rapidly as energy decreases, but then becomes much smaller at gamma-ray energy just below the binding energy of the K electron. This discontinuity is called the K edge below this energy the gamma ray does not have sufficient energy to dislodge a K electron. Below the K edge the interaction probability increases again until the energy drops below the binding energies of the L electron; these discontinuities are called the LI, LII, and LIII edges. The presence of these absorption edges is important for densitometry and x-ray fluorescence measurements.

Figure 2.7 Photoelectric mass attenuation coefficient of lead. <sup>(15)</sup>

#### 2.4.3 Compton scattering

Compton scattering is the process whereby a gamma ray interacts with a free or weakly bound electron ( $E_\gamma \gg E_b$ ) and transfers part of its energy to the electron (see Figure 2.8).

Conservation of energy and momentum allows only a partial energy transfer when the electron is not bound tightly enough for the atom to absorb recoil energy. This interaction involves the outer, least tightly bound electrons in the scattering atom. The electron becomes a free electron with kinetic energy equal to the difference of the energy lost by the gamma ray and the electron binding energy. Because the electron.

Figure 2.8 A schematic representation of Compton scattering. <sup>(15)</sup>

Binding energy is very small compared to the gamma-ray energy, the kinetic energy of the electron is very nearly equal to the energy lost by the gamma ray:

$$E_e = E_\gamma - E' \quad (2.10)$$

Where  $E_e$  = energy of scattered electron

$E_\gamma$  = energy of incident gamma ray

$E'$  = energy of scattered gamma ray.

Two particles leave the interaction site: the freed electron and the scattered gamma ray. The directions of the electron and the scattered gamma ray depend on the amount of energy transferred to the electron during the interaction. Equation 2.11 gives the energy of the scattered gamma ray; Figure 2.9 shows the energy of the scattered electron as a function of scattering angle and incident gamma-ray energy.

$$E' = m_0c^2 / \left(1 - \cos\phi + \frac{m_0c^2}{E}\right) \quad (2.11)$$

where  $m_0c^2$  = rest energy of electron = 511 keV

$\phi$  = angle between incident and scattered gamma rays (see Figure 2.9)

This energy is minimum for a head-on collision where the gamma ray is scattered  $180^\circ$  and the electron moves forward in the direction of the incident gamma ray. For this case the energy of the scattered gamma ray is given by Equation 2.12 and the energy of the scattered electron is given by Equation 2.13:

$$E'(min) = \frac{m_0c^2}{\left(2 + \frac{m_0c^2}{E}\right)} \quad (2.12)$$

$$\cong \frac{m_0c^2}{2} = 256 \text{ keV}; \text{ if } E \gg m_0c^2/2$$

$$E_e(max) = \frac{E}{1 + \frac{m_0 c^2}{2E}} \quad 2.13)$$

$$\cong E - \frac{m_0 c^2}{2} = E - 256 \text{ keV}; \text{ if } E \gg m_0 c^2 / 2$$

Figure 2.9 Energy of Compton-scattered electrons as a function of scattering angle and incident gamma-ray energy ( $E_\gamma$ ). The sharp discontinuity corresponds to the maximum energy that can be transferred in a single scattering. <sup>(15)</sup>

For very small angle scatterings ( $\phi \approx 0^\circ$ ), the energy of the scattered gamma ray is only slightly less than the energy of the incident gamma ray and the scattered electron takes very little energy away from the interaction. The energy given to the scattered electron ranges from near zero to the maximum given by Equation 2.13. When a Compton scattering occurs in a detector, the scattered electron is usually stopped in the detection medium and the detector produces an output pulse that is proportional to the energy lost by the incident gamma ray. Compton scattering in a detector produces a spectrum of output pulses from zero up to the maximum energy given by Equation 2.13. It is difficult to relate the Compton-scattering spectrum to the energy of the incident gamma ray. Figure 2.10 shows the measured gamma-ray spectrum from a monoenergetic gamma-ray source ( $^{137}\text{Cs}$ ). The full-

energy peak at 662 keV is formed by interactions where the gamma ray loses all of its energy in the detector either by a single photoelectric absorption or by a series of Compton scattering followed by photoelectric absorption. The spectrum of events below the full-energy peak is formed by Compton scattering where the gamma ray loses only part of its energy in the detector. The step near 470 keV corresponds to the maximum energy that can be transferred to an electron by a 662-keV gamma ray in a single Compton scattering. This step is called a Compton edge the energy of the Compton edge is given by Equation 2.13 and plotted in Figure 2.11. The small peak at 188 keV in Figure 12 is called a backscatter peak. The backscatter peak is formed when the gamma ray undergoes a large-angle scattering ( $\approx 180^\circ$ ) in the material surrounding the detector and then is absorbed in the detector. The energy of the backscatter peak is given by Equation 2.12, which shows that the maximum energy is 256 keV. The sum of the energy of the backscatter peak and the Compton edge equals the energy of the incident gamma ray. Both features are the result of large-angle Compton scattering of the incident gamma ray. The event contributes to the backscatter peak when only the scattered gamma ray deposits its energy in the detection it contributes to the Compton edge when only the scattered electron deposits its energy in the detector.

Figure 2.10 High-resolution spectrum of  $^{137}\text{Cs}$  showing full-energy photopeak, Compton edge, and backscatter peak from the 662-keV gamma ray. Events below the photopeak are caused by Compton scattering in the detector and surrounding materials.<sup>(15)</sup>

Because Compton scattering involves the least tightly bound electrons, the nucleus has only a minor influence and the probability for interaction is nearly independent of atomic number. The interaction probability depends on the electron density, which is proportional to  $Z/A$  and nearly constant for all materials. The Compton-scattering probability is a slowly varying function of gamma-ray energy (see Figure 2.5).

#### 2.4.4 Pair production

A gamma ray with energy of at least 1.022 MeV can create an electron-positron pair when it is under the influence of the strong electromagnetic field in the vicinity of a nucleus (see Figure 13). In this interaction the nucleus receives a very small amount of recoil energy to conserve momentum, but the nucleus is otherwise unchanged and the gamma ray disappears. This interaction has a threshold of 1.022 MeV because that is the minimum energy required to create the electron and positron. If the gamma ray energy exceeds 1.022 MeV, the excess energy is shared between the electron and positron as kinetic energy. This interaction process is relatively unimportant for nuclear material assay because most important gamma-ray signatures are below 1.022 MeV.

Figure 2.11 Energy of the Compton edge versus the energy of the incident gamma-ray.<sup>(15)</sup>

Figure 2.12 A schematic representation of pair production. <sup>(15)</sup>

The electron and positron from pair production are rapidly slowed down in the absorber. After losing its kinetic energy, the positron combines with an electron in an annihilation process, which releases two gamma rays with energies of 0.511 MeV. The lower energy gamma rays may interact further with the absorbing material or may escape. In a gamma-ray detector, this interaction often gives three peaks for a high-energy gamma ray (see Figure 2.13). The kinetic energy of the electron and positron is absorbed in the detector. One or both of the annihilation gamma rays may escape from the detector or they may both be absorbed. If both annihilation gamma rays are absorbed in the detector, the interaction contributes to the full-energy peak in the measured spectrum; if one of the annihilation gamma rays escapes from the detector, the interaction contributes to the single-escape peak located 0.511 MeV below the full-energy peak; if both gamma rays escape, the interaction contributes to the double-escape peak located 1.022 MeV below the full-energy peak. The relative heights of the three peaks depend on the energy of the incident gamma ray and the size of the detector. 'These escape peaks may arise when samples of irradiated fuel, thorium, and  $^{232}\text{U}$  are measured because these materials have important gamma rays above the pair-production threshold. Irradiated fuel is sometimes measured using the 2186-keV gamma ray from the fission-product  $^{144}\text{Pr}$ . The gamma-ray spectrum of  $^{144}\text{Pr}$  in Figure 2.13 shows the single- and double-escape peaks that arise from pair-production interactions of the 2186-keV gamma ray in a germanium detector.

Figure 2.13 Gamma-ray spectrum of the fission-product  $^{144}\text{Pr}$  showing single-escape (SE) and double-escape (DE) peaks (1674 and 1163) that arise from pair-production interactions of 2186-keV gamma rays in a germanium detector. <sup>(15)</sup>

Pair production is impossible for gamma rays with energy less than 1.022 MeV. Above this threshold, the probability of the interaction increases rapidly with energy (see Figure 7). The probability of pair production varies approximately as the square of the atomic number  $Z$  and is significant in high- $Z$  elements such as lead or uranium. In lead, approximately 20% of the interactions of 1.5-MeV gamma rays are through the pair-production process, and the fraction increases to 50% at 2.0 MeV. For carbon, the corresponding interaction fractions are 2% and 4%.

## 2.5 Ultrasonic testing

Ultrasonic Testing (UT) uses high frequency sound waves (between 0.5 and 15 MHz) to conduct examinations and make measurements. Besides its wide use in engineering application (such as flaw detection/evaluation, dimensional measurements, material characterization, etc.), ultrasonic are also used in the medical field (such as sonography, therapeutic ultrasound, etc.).

In general, ultrasonic testing is based on the capture and quantification of either the reflected waves (pulse-echo) or the transmitted waves (through-

transmission). Each of the two types is used in certain applications, but generally, pulse echo systems are more useful since they require one-sided access to the object being inspected. <sup>(16)</sup>

### 2.5.1 Basic principles

A typical pulse-echo UT inspection system consists of several functional units, such as the pulser/receiver, transducer and a display device. A pulser/receiver is an electronic device that can produce high voltage electrical pulses. Driven by the pulser, the transducer generates high frequency ultrasonic energy. The sound energy is introduced and propagates through the materials in form of waves. When there is a discontinuity (such as a crack) in the wave path, part of the energy will be reflected back from the flaw surface. The reflected wave signal is transformed into an electrical signal by the transducer and is displayed on a screen. Knowing the velocity of the waves, travel time can be directly related to the distance that the signal traveled. From the signal, information about the reflector location, size, orientation and other features can sometimes be gained.

### 2.5.2 Advantage and disadvantages <sup>(16)</sup>

The primary advantages and disadvantages when compared to other NDT methods are:

#### Advantages

- It is sensitive to both surface and subsurface discontinuities.
- The depth of penetration for flaw detection or measurement is superior to other NDT methods.
- Only single-side access is needed when the pulse-echo technique is used.
- It is highly accurate in determining the reflector position and estimating its size and shape.
- Minimal part preparation is required.
- It provides instantaneous results.
- Detailed images can be produced with automated systems.

- It is nonhazardous to operators or nearby personnel and does not affect the material being tested.
- It has other uses, such as thickness measurement, in addition to flaw detection.
- Its equipment can be highly portable or highly automated.

#### Disadvantages<sup>(16)</sup>

- Surface must be accessible to transmit ultrasound.
- Skill and training is more extensive than with some other methods.
- It normally requires a coupling medium to promote the transfer of sound energy into the test specimen.
- Materials that are rough, irregular in shape, very small, exceptionally thin or not homogenous are difficult to inspect.
- Cast iron and other coarse grained materials are difficult to inspect due to low sound transmission and high signal noise.
- Linear defects oriented parallel to the sound beam may go undetected.
- Reference standards are required for both equipment calibration and the characterization of flaws.

## 2.6 X-ray sources and x-ray detectors

### - X-ray sources<sup>(17) (18) (19)</sup>

X-ray sources can be divided into 2 groups i.e. x-ray tubes and isotopic x-ray sources. The x-ray tubes produce x-rays from acceleration of electron in vacuum tube. Continuous x-rays are emitted from interaction of fast electrons with the anode target which are so called “bremsstrahlung” in German or “braking radiation” in English. This research intends to use an isotopic x-ray source due to its compact size and constant output. Moreover, it does not require electricity to generate x-rays. The isotopic x-ray sources are mostly radioactive isotopes produced by nuclear reactors and particle accelerators. There are various choices to be selected for

specific applications depending mainly upon the required energy range. Common x-ray isotopic sources are tabulated in Table 2.1

Table 2.1 Common low energy x-ray and gamma-ray sources

Isotope	Half-life	Major x-ray energy emitted and relative intensity
$^{55}\text{Fe}$	2.7 years	Mn K x-rays 5.90-6.49 keV (26%)
$^{57}\text{Co}$	0.74 year	Fe K x-rays 6.4-7 keV (55%) 14.41 keV gammas (9.5%) 122 keV gammas (85.6%) 136 keV gamma (10.6%)
$^{109}\text{Cd}$	1.24 years	Ag K x-rays 22.1 – 25.0 keV (100%) 88 keV gammas (3.6%)
$^{238}\text{Pu}$	87.7 years	U L x-rays 13.6-20.1 keV (13%) 43.5 keV gammas (0.39%)
$^{241}\text{Am}$	243 years	Np L x-rays 14-21 keV (40%)

*Note: The energy below 10 keV is available only when Be is used as the source window*

This research prefers an x-ray source that gives low energy x-rays and/or gamma-rays in 10 – 50 keV range so that photons can penetrate through liquid contained in bottle and still give difference in transmitted intensity for different kinds of liquid. From the data in Table 2.1,  $^{109}\text{Cd}$ ,  $^{238}\text{Pu}$  and  $^{241}\text{Am}$  are appropriate.

- X-ray detectors<sup>(18) (20)</sup>

At present, various types of detectors are available for detection of x-rays and gamma-rays. They are categorized into 3 groups including gas proportional, scintillation and semiconductor detectors as summarized in Table 2.2. Their detection efficiencies are illustrated in figure 2.14 – 2.15. It must be kept in mind that the efficiency at low energy is dependent upon thickness of the detector window while at high energy is dependent upon thickness and diameter of detector material.

Table 2.2 Detectors for x-rays and gamma-rays

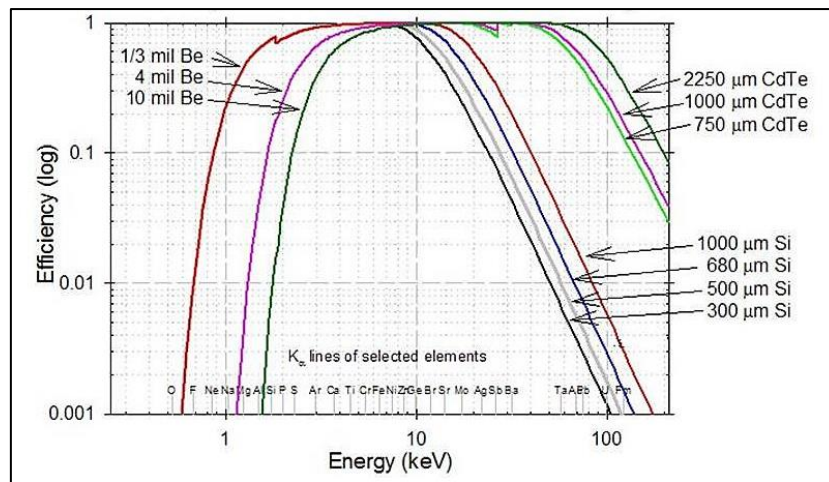

Type of detector	Characteristics	Example
Proportional counter	good resolution, suitable for energy up to about 30 keV	Ar-filled, Kr-filled, Xe-filled detectors
Scintillation detector	poor energy resolution, available for energy from about 10 keV up to several MeV depending mainly on thickness of the crystal	- NaI(Tl) for 10 keV-10 MeV - Bismuth germanate(BGO) for 100 keV up to 10 MeV, poorer energy resolution, higher efficiency for high energy range
Semiconductor	excellent resolution, available for energy from a few keV up to several MeV depending on detector thickness and material	- Si(Li) for <1 keV up to 30 keV* - HPGe for 1 keV up to 10 MeV* - CdTe for 1 keV up to 100 keV** - CdZnTe for 10 keV up to 1 MeV** - Si PIN photodiode for 1 keV up to 30 keV**

Note: \* needs liquid nitrogen, electrical or mechanical cooling

\*\* compact size, only Peltier cooling is sufficient

## CHAPTER III

### EXPERIMENT

Factors that affected in the linear attenuation coefficient calculation were studied including x-ray energy, bottle diameter, bottle thickness and bottle types. The Lambert's Law was used for calculation of the linear attenuation coefficient of liquid that can be used to identify or classify types of liquid.

#### Equipment and materials:

- $^{238}\text{Pu}$  (13.6, 17.2, 20.1 and 43.5 keV) radioisotopic point source
- $^{241}\text{Am}$  (59.5 keV) radioisotope point source
- $^{57}\text{Co}$  (122 keV) radioisotope point source
- Copper collimators of aperture 5 mm  $\phi$
- CdTe-diode detector (detector areas 5 mm x 5 mm) model XR-100T with preamplifier
- Power supply
- ORTEC EASY-MCA 2k Multichannel Analyzer
- INSPEX Ultrasonic thickness gauge model IPX -251S
- Vernier caliper
- PET and HDPE plastic bottles
- Glass bottles
- Metal cans (aluminum and steel)
- Beverages and hazardous liquids

Figure 3.1 Experimental setup for determining the linear attenuation coefficients of liquids

The diagram of experimental setup for measuring the linear attenuation coefficient of liquids by using low energy x-ray transmission technique is shown in Figure 3.1. Three point sources including 100 mCi  $^{241}\text{Am}$  (59.54 keV), 10 mCi  $^{238}\text{Pu}$  (13.6, 17.2, 20.1 and 43.5 keV) and 10 mCi  $^{57}\text{Co}$  (122 keV) were used to generate primary x-rays and gamma-rays in the range of about 13 to 122 keV. Copper collimators having aperture of 5 mm were selected for the source and the detector, instead of Pb, to avoid interference from Pb x-rays. A 5 mm x5 mm CdTe-diode detector model XR-100T-CeTe coupled with an ORTEC EASY-MCA 2k multichannel analyzer was employed for collecting x-ray and gamma-ray intensity. The source and the detector are positioned on the opposite side of the bottle under inspection to obtain transmitted x-ray and gamma-ray intensities.

### 3.1 Effect of x-ray energy

Theoretically, the linear attenuation coefficients of elements have large difference at low energy and get closer at high energy. Thus, in the first experiment, we experimented with three available radioisotope sources to observe their sensitivities and penetrating power.

The sources including  $^{238}\text{Pu}$  (13.6 keV, 17.2 keV, 20.1 keV),  $^{241}\text{Am}$  (59.5 keV) and  $^{57}\text{Co}$  (122 keV) were used. The bottle was placed between the source and the

detector as in figure 3.1 then  $I_0$  was measured near the top of the bottle where there was no liquid. The transmitted intensity ( $I_x$ ) was measured at any position where there was liquid in the bottle. The counting time was 300 seconds. The tested samples were drinking water, soft drink, ethanol70%, kerosene, diesel and bensene95 contained in the same type of PET plastic bottle with outside diameter of 3.1 cm and bottle thickness of 0.06 cm (measured by Vernier caliper). The collimator was designed in the way that all the three sources could be put together allowing single measurement for all energy ranges. The experimental setup is shown in Figure 3.3

Figure 3.2 Copper collimator of aperture 2, 3 and 5 mm.

Figure 3.3 Experimental setup for investigating the effect of x-ray energy on the obtained linear attenuation coefficients of liquid

$$(S_1 \text{ is } ^{238}\text{Pu}, S_2 \text{ is } ^{241}\text{Am} \text{ and } S_3 \text{ is } ^{57}\text{Co})$$

### 3.2 Effect of bottle diameter

Because there are many kinds of liquid bottles such as plastic and glass bottles with different diameters ranging from approximately 2 to 10 cm. To investigate the effect of bottle diameter, PET bottles with diameters of 2.26, 3.10, 3.33, 3.82, 4.96 and 7.40 cm were first selected. The bottles containing drinking water, soft drink, beer, ethanol (70%), kerosene, diesel, benzene 95, gasohol 95, gasohol E20 and gasohol E85 were placed between the source and the detector as in figure 3.1 for measurements of  $I_0$  and  $I_x$  one after the other. Diameter and thickness of the PET bottles were measured by a Vernier caliper in order to find the exact liquid thickness ( $x$ ). Only the  $^{238}\text{Pu}$  source was used in this experiment because it gave satisfactory sensitivity in the previous experiment in comparison to the other two sources. The  $^{57}\text{Co}$  gamma-ray energies (122 and 136 keV) were too high for those ranges of liquid thickness resulting in decreasing of the sensitivity. The available  $^{241}\text{Am}$  source used in the previous experiment had too thick window allowing only 59.5 keV gammas to come out which was also too high for those range of liquid thickness. The energies of Np L x-rays from  $^{241}\text{Am}$  were actually very close to those from the  $^{238}\text{Pu}$  but the source window had to be made of thin beryllium (Be) to allow them to come out. Thus, the  $^{57}\text{Co}$  and  $^{241}\text{Am}$  sources were not used in this and next experiments.

From the above experiments, it was found that when the bottle diameter went beyond about 5 cm the transmitted intensity ( $I_x$ ) through water, soft drink and beer was very low. Therefore, in the next experiment, two pieces of steel plate were placed in parallel 4.5 cm apart to limit the measurement of large bottle to thickness of liquid not more than 4.5 cm as illustrated in figure 3.5. The liquid samples were water, ethanol (70%) and kerosene contained in six types of plastic bottles having diameters of 4.9, 5.1, 5.5, 6.1, 6.2 and 6.3 cm as shown in figure 3.4. The transmitted intensity ( $I_x$ ) and  $I_0$  were measured the same way as in the previous experiments.

Figure 3.4 PET bottles having diameters of 4.9 to 6.3 cm

Figure 3.5 The Experiment set-up to limit the measurement thickness at 4.5 cm

### 3.3 Effect of bottle thickness

A 3.76 cm diameter PET bottle having thickness of 0.08 cm was selected as the liquid container. Plastic sheet with a thickness of 0.026 cm was inserted inside the liquid bottle one after the other to investigate the effect of plastic thickness on the obtained linear attenuation coefficient. Liquid samples were water, ethanol (70%) and kerosene. The obtained  $I_0$  and  $I_x$  were then used to calculate the linear

attenuation coefficient of liquid at each plastic thickness. It should be noted that liquid thickness at each total plastic thickness was obtained from the difference of outside diameter of the bottle and the total thickness of plastic.

Figure 3.6 Experimental setup to investigate the effect of bottle thickness on the obtained linear attenuation coefficient of liquid

### 3.4 Effect of bottle types

There are various beverage products contained in different types of bottle such as plastic, glass and can. The obtained linear attenuation coefficient of liquid should be independent of the bottle type. Therefore, the purpose of this experiment was to investigate whether the bottle type would have effect on the obtained linear attenuation coefficient of liquid.

Types of bottle:

*Polyethylene Terephthalate (PET) and High-density polyethylene (HDPE)* <sup>(22)</sup>

Polyethylene Terephthalate sometimes absorbs odors and flavors from foods and drinks that are stored in them. Items made from this plastic are commonly recycled. PET(E) plastic is used to make many common household items like beverage bottles, medicine jars, rope, clothing and carpet fiber. High-Density

Polyethylene products are very safe and are not known to transmit any chemicals into foods or drinks. HDPE products are commonly recycled. Items made from this plastic include containers for milk, motor oil, shampoos and conditioners, soap bottles, detergents, and bleaches.

Figure 3.7 The Society of the Plastics Industry (SPI) symbols. <sup>(23)</sup>

Other types of plastic are showed in figure 3.7. Manufacturers place an SPI code, or number, on each plastic product, usually molded into the bottom. This guide provides a basic outline of the different plastic types associated with each code number.

*Soda-lime glass* <sup>(24)</sup>

For every drinking glass is soda-lime glass. Soda-lime glass is the most commonly available glass and contains both sodium and calcium. This type of glass is used for windows in buildings, bottles and jars. Composition of soda-lime glass is shown in Table 3.1

Table 3.1 Composition of soda-lime glass<sup>(24)</sup>

SiO <sub>2</sub>	72.60%
Na <sub>2</sub> O	13.90%
CaO	8.40%
MgO	3.90%
Al <sub>2</sub> O <sub>3</sub>	1.10%
K <sub>2</sub> O	0.60%
SO <sub>3</sub>	0.20%
Fe <sub>2</sub> O <sub>3</sub>	0.11%

*Aluminum and steel cans*<sup>(25)</sup>

There are two types of beverage cans. Major metal materials are aluminum and steel. Major cans are classified into two types: 3-piece cans consisting of three components of (1) a bottom lid, (2) a cylindrical body and (3) a top lid (a lid with a lip [an opening] for a beverage can), and 2-piece cans consisting of two components of (1) a body integrated with a bottom lid and (2) a lid with a lip (an opening). 2-Piece cans made from aluminum and use for a soft drink, beer, tea or fruit juice while 3-piece cans made from steel and use for beverages with milk, coffee or tea.

This experiment studied the effect of bottle types including PET plastic bottles, HDPE plastic bottles, glass bottles, aluminum cans and steel cans on the obtained linear attenuation coefficients. The linear attenuation coefficient of bottle material was determined and used to estimate the bottle thickness without measurement of the  $I_0$  but  $I_0$  was obtained from equation 3.1.

For empty bottle or at the empty portion of the bottle, the bottle thickness can also be calculated from equation 3.1 below.

$$I_0 = I_{\text{Air}} e^{-\mu_b \cdot x_b} \quad (3.1)$$

Where  $I_0$  is transmitted intensity through the bottle with no liquid

$I_{\text{Air}}$  is the photon intensity through the air

$\mu_b$  is linear attenuation coefficient of the bottle (cm<sup>-1</sup>)

$x_b$  is bottle thickness (cm)

Figure 3.8 Experimental setup for determining of the linear attenuation coefficient of bottle ( $\mu_{\text{bottle}}$ )

#### 3.4.1 Bottle with air portion inside

The linear attenuation coefficients of liquids in plastic bottles and glass bottles with air portion inside the bottles were calculated by using  $\mu_{\text{bottle}}$  obtained from equation 3.1. Then liquid thickness was calculated by subtracting the bottle thickness from the bottle diameter. Finally, the linear attenuation coefficients of liquids were calculated by using equation 3.2

$$I_x = I_0 e^{-\mu x} \quad 3.2$$

Where  $I_x$  is transmitted intensity through the bottle and liquid

$I_0$  is transmitted intensity through the bottle with no liquid

$\mu$  is linear attenuation coefficient of the liquid ( $\text{cm}^{-1}$ )

$x$  is liquid thickness (cm)

### 3.4.2 Bottle without air portion

Plastic bottle without air portion inside,  $I_0$  could not be measured. The attenuation of x-rays by the bottle walls could be calculated from the linear attenuation coefficient of the plastic and its estimated thickness. It was expected that discrepancy of the estimated thickness from the actual value would have insignificant effect of the calculated linear attenuation coefficients of the liquids. This was because plastic had low linear attenuation coefficient as that of liquid and its thickness was small in comparison to liquid thickness. The estimated thickness of 0.02 and 0.05 cm were used in calculation of the linear attenuation of liquid contained in PET and HDPE bottles respectively. In contrast, for glass bottles, glass wall thickness was found to be in the range of 3- 5 mm and had high linear attenuation coefficient. Estimation of glass thickness may cause large error in calculation of the linear attenuation coefficient of liquid contained in the bottle. Therefore, the glass thickness was measured using an ultrasonic thickness gauge when there was no air portion for measurement of  $I_0$ . The thicknesses of glass bottles measured by the ultrasonic thickness gauge and the x-ray transmission technique were tabulated in table 4.28. Finally, six types of glass bottles containing different kinds of liquid were selected for the test. The linear attenuation coefficients of liquids contained the glass bottles were compared with those obtained from other kinds of bottle.

For metal cans like aluminum and steel cans. The linear attenuation coefficients were so high in comparison with those of liquids. The linear attenuation coefficients of aluminum cans and steel cans were determined and used for calculation of  $I_0$ . Fortunately, thicknesses of aluminum and steel cans were found to be about 0.01 and 0.02 cm respectively which made calculation of attenuation by the aluminum and steel walls simpler.

Various kinds of commercial Liquid in PET, HDPE and glass bottles as well as aluminum and steel cans were tested using the above mentioned procedures including drinking water, orange juice, milk, green tea and coffee. The results are presented in Chapter 4.

## CHAPTER IV

### RESULTS AND DISCUSSION

The experiments was carried out by measurement of the transmitted intensity of x-rays and gamma-rays through various kinds of liquid contained in different types of bottles with varying materials, thicknesses and diameters. The CdTe detector gave good energy resolution in measurement of the U L x-rays emitted from  $^{238}\text{Pu}$  source at 13.6, 17.2 and 20.1 keV. The transmitted x-ray spectra through 3 kinds of liquid contained in plastic bottles is shown in Figure 4.1.

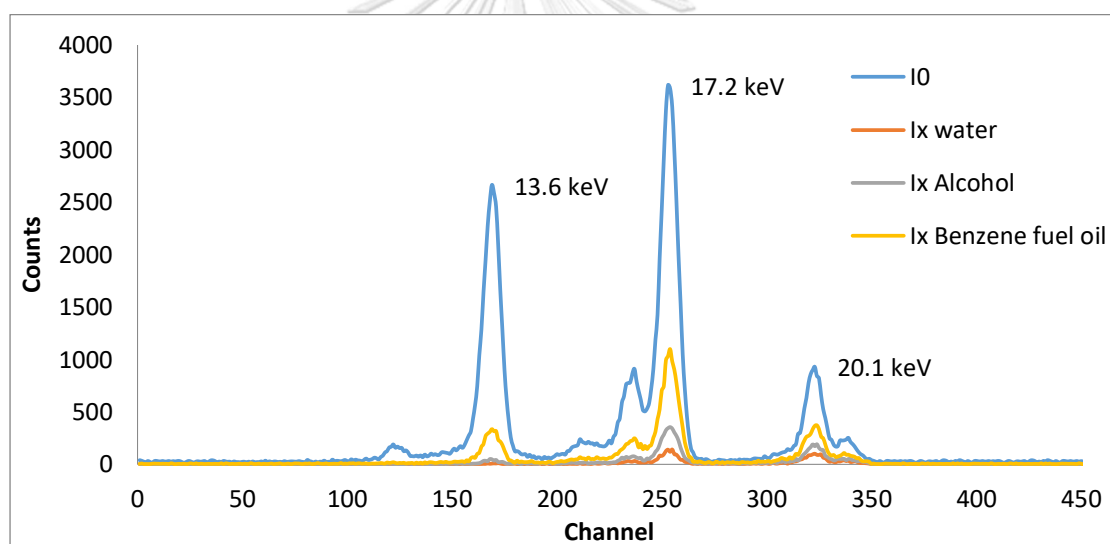

Figure 4.1 Transmitted x-ray spectra from  $^{238}\text{Pu}$  source through water, alcohol and fuel oil

The primary results showed that transmitted intensity through water, alcohol and fuel oil were very different at this low energy range which indicated potential use of this proposed technique for screening liquid at airports. The linear attenuation coefficients of liquids calculated by using the NIST mass attenuation coefficient table and the values obtained from this preliminary experiment are shown in table 4.1 and 4.2. Discrepancies of the values obtained in the experiment from the calculated values are mainly due to interferences by neighboring x-ray peaks as can be seen in Figure 4.1 particularly at 17.2 and 20.1 keV peaks.

#### 4.1 Effect of x-ray energy on the obtained $\mu$

The linear attenuation coefficient ( $\mu$ ) is a basic parameter to identify matter. The total mass attenuation coefficient is sum of the product of mass attenuation coefficient and weight fraction of all elements as in equation 2.7. Theoretically, the attenuation coefficient is high at low x-ray energy and decreases with increasing of x-ray energy. The mass attenuation coefficient ( $\mu/\rho$ ) of some elements from the NIST is illustrated in Figure 4.2.

Figure 4.2 Mass attenuation coefficients ( $\text{cm}^2/\text{g}$ ) of some elements from the NIST

The transmitted intensity ( $I_x$ ) of x-rays and gamma-rays from  $^{238}\text{Pu}$ ,  $^{241}\text{Am}$  and  $^{57}\text{Co}$  radioisotope sources through various kinds of liquid samples contained in 3.1 cm diameter PET bottles were measured. The results are tabulated in Table 4.3. It should be noticed that 13.6 keV x-ray almost cannot penetrate water and soft drink even the bottle is rather small in diameter.

Table 4.3 Showing the transmitted intensities of x-rays and gamma-rays through various kinds of liquids contained in 3.1 cm diameter PET bottles

Types of liquid	$I_0$ and $I_x$ through various kinds of liquid at different energies				
	13.6 keV	17.2 keV	20.1 keV	59.5 keV	122 keV
$I_0$	129487	261265	63812	135346	20089
$I_x$ Drinking water	274	9548	7673	74628	12305
$I_x$ Soft Drink	186	8022	6664	71867	12288

Benzene 95	0.6652±0.0027	0.3835±0.0013	0.2685±0.0024	0.1442±0.0015	0.1245±0.0037

Figure 4.3 The obtained linear attenuation coefficients of liquids versus photon energy

The results demonstrate that the linear attenuation coefficients of all sample liquids are high at low energy and decrease rapidly from 10 to 20 keV. Difference of the linear attenuation coefficients of different kinds of liquid are also large at low energy and become closer toward higher energy. For example, the linear attenuation coefficients of drinking water, Ethanol (70%) and Benzene 95 at X-ray energy 13.6 keV are  $2.0665 \pm 0.0203$ ;  $1.4507 \pm 0.0082$  and  $0.6652 \pm 0.0027$  while at 122 keV are  $0.1645 \pm 0.0038$ ,  $0.1405 \pm 0.0038$  and  $0.1245 \pm 0.0037$  respectively.

CHULALONGKORN UNIVERSITY

#### 4.2 Effect of bottle diameter on the obtained $\mu$

The linear attenuation coefficients of drinking water, soft drink, beer, ethanol (70%), kerosene, Diesel, Benzene 95, gasohol 95, gasohol E20 and gasohol E85 fuel oil contained in PET bottles of different diameters were determined at different energies. The results are shown in the following table 4.5 to 4.12.

Table 4.5 The linear attenuation coefficients of drinking water contained in bottles having diameters 2.26 – 7.40 cm

The results show that the linear attenuation coefficients of the same kind of liquid obtained from different bottle sizes are very close. But when the bottle diameter becomes larger than about 5 cm, the transmitted intensity of the water-based liquids such as drinking water, soft drink, and beer was too low to calculate the linear attenuation coefficient at 13.6 keV. However, higher energy such as 20.1 keV can penetrate the water-based liquids but the linear attenuation coefficients become closer. The linear attenuation coefficient of liquids at 13.6 keV and 20.1 keV contained in various bottle diameters are presented in Figure 4.4 and Figure 4.5.

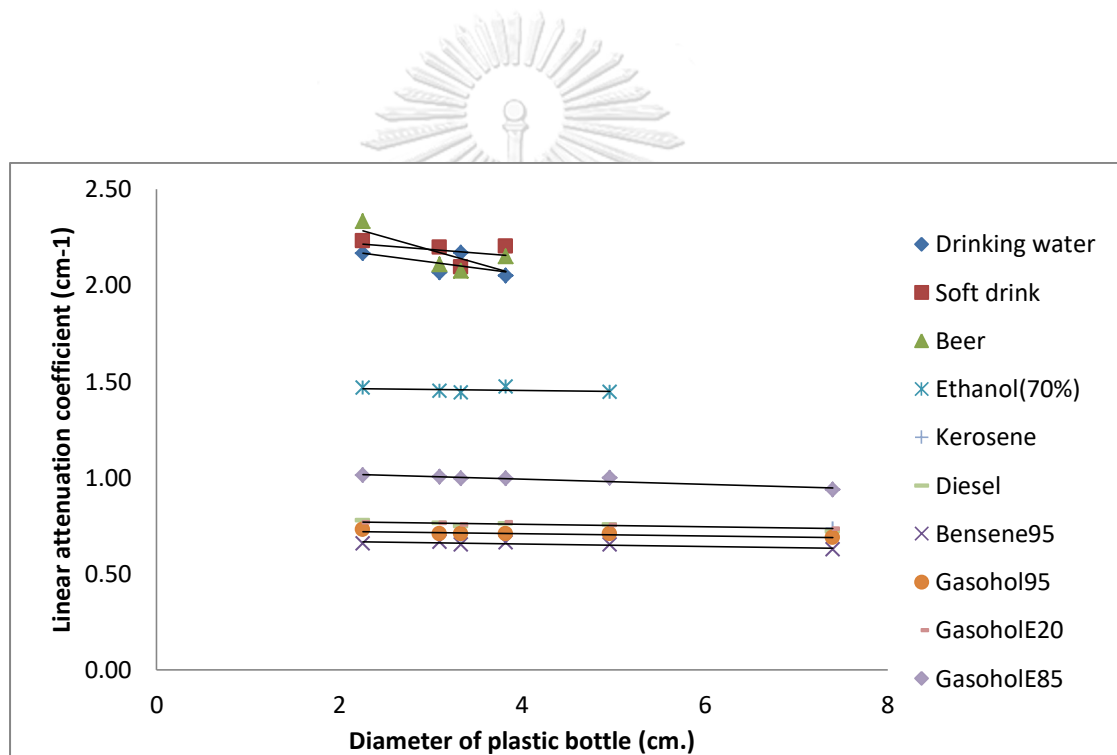

Figure 4.4 The linear attenuation coefficients of liquids contained in various bottle diameters for 13.6 keV x-rays

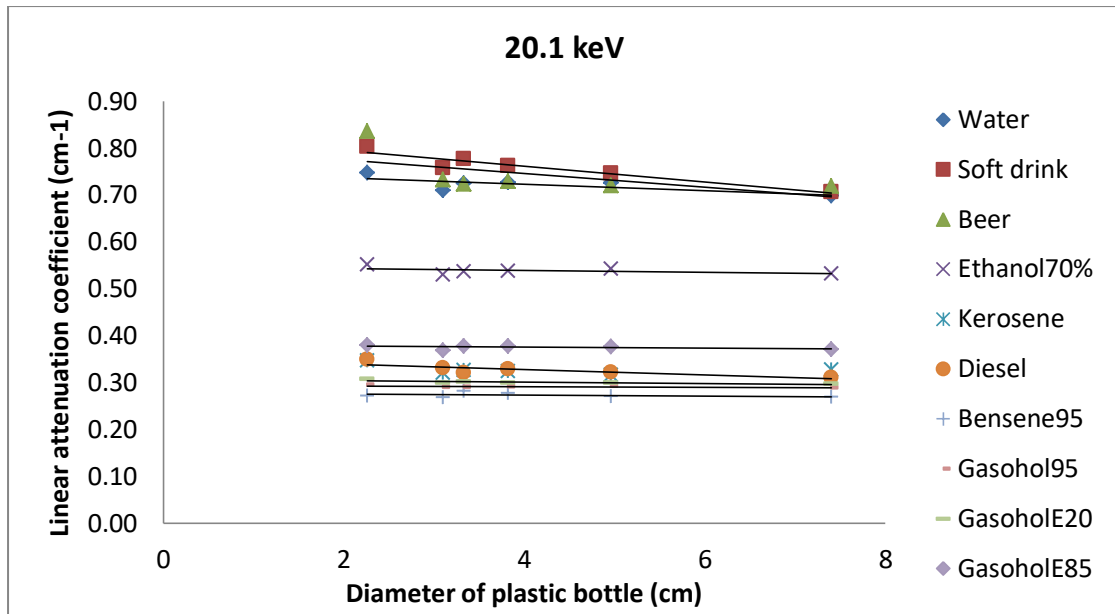

Figure 4.5 The linear attenuation coefficients of liquids contained in various bottle diameters for 20.1 keV x-rays

When liquid thickness was fixed to 4.5 cm, the linear attenuation coefficients of water, ethanol (70%) and kerosene contained in different types of bottles were found to be close to the values obtained earlier. However, they tend to gradually increase with increasing of the bottle diameter which most probably caused by curvature and thickness of the bottles. For example, the linear attenuation coefficient of water in bottle A (4.9 cm  $\phi$ ) and bottle F (6.3 cm  $\phi$ ) at 17.2 keV are 1.1773 and 1.2184  $\text{cm}^{-1}$  respectively. But the average linear attenuation coefficients of water, ethanol (70%) and kerosene still have large differences. For example, the average linear attenuation coefficients of water, ethanol (70%) and kerosene at 17.2 keV are  $1.2008 \pm 0.0167$ ,  $0.8374 \pm 0.0196$  and  $0.4769 \pm 0.0139$  respectively.

#### 4.3 Effect of bottle thickness on the obtained $\mu$

Since the bottles not only have difference in diameter but also the thickness. For a thin plastic bottles like drinking water bottles or soft drink bottles, the thickness can be ignored because the linear attenuation coefficients of plastics fall in the same range as the linear attenuation coefficients of liquids. Conversely, thick bottles may affect the linear attenuation coefficients of liquids if it is not taken into account in measurement or in calculation. The transmitted intensity and linear attenuation coefficients of water, ethanol (70%) and kerosene at various plastic thicknesses are shown in table 4.18.

Table 4.18 Transmitted intensity and the linear attenuation coefficients of water in various plastic thicknesses

Thickness of plastic (cm)	Transmitted Intensity			Linear attenuation coefficient ( $\text{cm}^{-1}$ ) of water		
	13.6 keV	17.2 keV	20.1 keV	13.6 keV	17.2 keV	20.1 keV

The results show that when thickness of the bottle increases from 0.16 to 0.42 cm, the transmitted intensity decreases accordingly but the linear attenuation coefficient of water is still statistically constant. This means, for plastic bottles, the thickness does not have to be accurately known. Estimation of thickness should be enough for satisfactorily determining the linear attenuation coefficient of liquid. When plastic bottles, having diameter of 3.9 cm and thickness of 0.06 cm, filled with different kinds of liquids were tested in determining the linear attenuation coefficients of liquids by using estimated thickness the obtained value for water based liquids were statistically constant. However, the values of alcohol and fuel oil group tended to have little decrease when the estimated thickness went far beyond the actual value (as shown in Table 4.21 and Figure 4.6). This is mainly because the linear attenuation coefficients of plastic are greater than those of alcohol and fuel oil. In practice, user can actually estimate the bottle thickness from his/her experience or from the bottle data base. By using a Vernier caliper, the average thickness of commercial PET and HDPE plastic bottles were found to be about 0.02 cm and 0.05 cm respectively.

Table 4.21 The linear attenuation coefficient of liquids obtained by using the estimated thickness of plastic bottles.

Types of liquid	Linear Atten. Coef. for estimate plastic thickness at 17.2 keV

<b>Average <math>\mu_{\text{glass}}</math></b>		<b>12.4338±0.0664</b>	<b>7.6402±0.0581</b>	<b>1.0936±0.0601</b>

Table 4.24 The average linear attenuation coefficients of metal cans

Types of can	Average linear attenuation coefficient ( $\text{cm}^{-1}$ ) of can			
	13.6 keV	17.2 keV	20.1 keV	43.5 keV
Aluminum can	30.8244 $\pm 0.3237$	15.3854 $\pm 0.1679$	9.6949 $\pm 0.4472$	1.3640 $\pm 0.3914$
Steel can	$I_x$ is too low for calculation		145.2940 $\pm 2.7782$	18.4622 $\pm 0.6844$

The results show that average linear attenuations of PET and HDPE bottles are quite different from 1.1 to  $2.4 \text{ cm}^{-1}$  while the average value is about  $1.7 \text{ cm}^{-1}$  at 13.6 keV. However, the plastic bottle thickness only has little effect on the linear attenuation coefficient of liquid. This is because plastic is so thin in comparison to thickness of liquid and the linear attenuation coefficient is relatively low. The estimated thickness will give satisfactory result.

The glass bottles are thick and the linear attenuation of glass bottle is found to be very high. For example, at 17.2 keV the average value is  $12.4338 \pm 0.0664 \text{ cm}^{-1}$  while it is only  $0.8621 \pm 0.0994 \text{ cm}^{-1}$  for plastic bottles. The 13.6 keV x-rays cannot penetrate the glass bottles. Thus, thickness of glass bottle needs to be measured by some means. The values obtained by x-ray transmission technique and by ultrasonic thickness gauge are shown in Table 4.25.

Table 4.25 Comparison thicknesses of glass bottle measured by ultrasonic thickness gauge and by x-ray transmission technique

Types of glass	Thickness from UT (cm)	x-ray transmission technique (cm)	% difference
Bottle glass 1	$0.4290 \pm 0.0004$	$0.4365 \pm 0.0270$	1.748
Bottle glass 2	$0.4050 \pm 0.0004$	$0.4048 \pm 0.0085$	0.049
Bottle glass 3	$0.3600 \pm 0.0004$	$0.3707 \pm 0.0196$	2.972
Bottle glass 4	$0.3740 \pm 0.0004$	$0.3683 \pm 0.0050$	1.524
Bottle glass 5	$0.3610 \pm 0.0004$	$0.3796 \pm 0.0173$	5.152
Bottle glass 6	$0.3500 \pm 0.0004$	$0.3674 \pm 0.0191$	4.971

The results show that % different from ultrasonic thickness gauge and calculation is lower than 5%. Therefore, for the bottle with air gap inside can use ultrasonic thickness gauge or calculation by transmission technique.

#### 4.4.1 Result of bottle with air portion

The linear attenuation coefficients of liquids contained in plastic bottles with air portion were calculated and presented in the following tables.

Table 4.26 The linear attenuation coefficients of liquids contained in 3.9 cm diameter PET bottle with air portion for measurement of  $I_0$

Types of liquid	Linear attenuation coefficient ( $\text{cm}^{-1}$ )			
	13.6 keV	17.2 keV	20.1 keV	43.5 keV
Water	too low $I_x$	$1.1037 \pm 0.0027$	$0.7297 \pm 0.0026$	$0.2369 \pm 0.0060$
Ethanol(95%)	$1.2095 \pm 0.0045$	$0.6578 \pm 0.0012$	$0.4589 \pm 0.0016$	$0.1889 \pm 0.0056$
H <sub>2</sub> O <sub>2</sub> (18%)	$I_x$ low to cal.	$1.1947 \pm 0.0032$	$0.7955 \pm 0.0029$	$0.2665 \pm 0.0062$
Acetone	$1.0236 \pm 0.0032$	$0.5559 \pm 0.0010$	$0.3941 \pm 0.0015$	$0.1793 \pm 0.0055$
Kerosene	$0.7148 \pm 0.0018$	$0.4227 \pm 0.0008$	$0.3176 \pm 0.0013$	$0.1815 \pm 0.0055$
Diesel fuel oil	$0.7388 \pm 0.0019$	$0.4292 \pm 0.0008$	$0.3217 \pm 0.0013$	$0.1719 \pm 0.0055$
Methanol(70%)	$1.2372 \pm 0.0048$	$0.6657 \pm 0.0012$	$0.4607 \pm 0.0016$	$0.1841 \pm 0.0055$
H <sub>2</sub> O <sub>2</sub> (12%)	$I_x$ low to cal.	$1.1855 \pm 0.0031$	$0.7838 \pm 0.0028$	$0.2561 \pm 0.0061$
Glycerin	$2.0163 \pm 0.0208$	$1.1215 \pm 0.0028$	$0.7624 \pm 0.0027$	$0.2886 \pm 0.0063$

E20 fuel oil		12.0624±0.1294	4.5063±0.0107
Acetone		7.9397±0.0832	3.5247±0.0104

The results show that linear attenuation coefficients of liquids can be divided into 2 groups. The first group was water-based such as drinking water and H<sub>2</sub>O<sub>2</sub> (12-18%). This group had a linear attenuation coefficient more than 1.1 cm<sup>-1</sup> at 17.2 keV. The second group was a hazardous group as ethanol (70%), ethanol (95%), Methanol (70%), gasohol E85, kerosene and fuel oil which have a linear attenuation coefficient lower than 1.0 cm<sup>-1</sup> at x-ray energy 17.2 keV.

Low energy x-ray at 13.6 keV has the highest linear attenuation coefficient and has large difference between elements but for a bottle diameter more than 3 cm linear attenuation coefficients for water-based liquids could not be calculated because water-based liquids had a high linear attenuation coefficient at low energy then the transmitted intensity could not penetrate through water-based liquids.

The ratio of the transmitted intensity of liquids per the transmitted intensity of water is used to make a clear difference between different kinds of liquid. The ratio of the bottle diameter 3.9 cm was shown in Figure 4.7 and Figure 4.8.

The bottles which diameter 3.9 cm has transmitted intensities of ethanol (70%) and gasohol 95 compared with water ( $I_{XL}/I_{XW}$ ) are approximately 3.5 and 13.7 respectively at 17.2 keV. When the bottles become larger, the  $I_{XL}/I_{XW}$  values become higher at each energy peak. For example at diameter 4.5 cm. and 17.2 keV  $I_{XL}/I_{XW}$  values of ethanol (70%) and gasohol95 is 4.5 and 22.7 respectively. It should be noted that the transmitted intensity at 17.2 keV peak is only about 1.53 % for water contained in 3.9 cm diameter bottle but for ethanol (70%) and gasohol 95 are about 5.5 and 21.2 % respectively. It is of importance to note the differences of  $I_{XL}/I_{XW}$  values of various fuel oils decreases with increasing of a percentage of ethanol. The  $I_{XL}/I_{XW}$  value of ethanol is much lower than those of the fuel oils while diesel oil stays in between alcohol and gasohol 95. The experiment also shows that water-based liquids like a soft drink, fruit juice, syrup and saline solution have  $I_{XL}/I_{XW}$  values less than 1.0 due to absorption by sugar, salt, and other added substances.

Figure 4.7 Ratio of  $I_{XL}/I_{XW}$  at 17.2 keV in bottle diameter 3.9cm

Figure 4.8 Ratio of  $I_x/I_{xW}$  at 20.1 keV in bottle diameter 3.9cm

Water, H<sub>2</sub>O<sub>2</sub> (18%), diesel, acetone, kerosene and ethanol (70%) were selected for measuring linear attenuation coefficient of liquids in the glass bottle with air inside and the results are shown in table 4.28.

Table 4.28 The linear attenuation coefficient of liquids in glass bottles

Types of liquid	Linear attenuation coefficient (cm <sup>-1</sup> )			
	13.6 keV	17.2 keV	20.1 keV	43.5 keV
Water		Ix is too low to calculate for calculation	0.6033±0.0123	0.2222±0.0061
H <sub>2</sub> O <sub>2</sub> (18%)			0.6673±0.0132	0.2576±0.0063
Diesel		0.4307±0.0063	0.3183±0.0049	0.1649±0.0052
Acetone		0.5318±0.0088	0.3861±0.0059	0.1555±0.0050
Kerosene		0.3984±0.0064	0.2949±0.0047	0.1551±0.0050
Ethanol (70%)		0.7806±0.0158	0.4721±0.0070	0.1819±0.0051

The Glass bottle has a high linear attenuation coefficient. Thus the intensity of low energy X-ray such as 13.7 keV cannot transmit and calculate the linear attenuation of liquids in the glass bottle. For 17.2 keV X-ray energy, a photon can transmit the glass but for water-based liquids, it cannot transmit through glass and liquids. In contrast, photon energy 17.2 keV can transmit the flammable liquids such as ethanol or fuel oil in the glass bottle. Higher energy X-ray (20.1 and 43.5 keV) has a high penetration then linear attenuation coefficient can be calculated.

Theoretical, linear attenuation coefficient of the same liquid in other types of bottles must be the same value. Therefore, the linear attenuation coefficient of liquids contained in glass and plastic bottles were compared and shown in figure 4.9 and figure 4.10. The results show that the linear attenuation coefficients of liquids in plastic bottles were a little higher than in the glass bottles. This was because the transmitted intensity of x-rays at energy was low. Higher x-ray energy may be better for the glass bottles with diameter around 5-6 cm but the intensity of 43.5 keV x-rays from  $^{238}\text{Pu}$  was too low for this application.

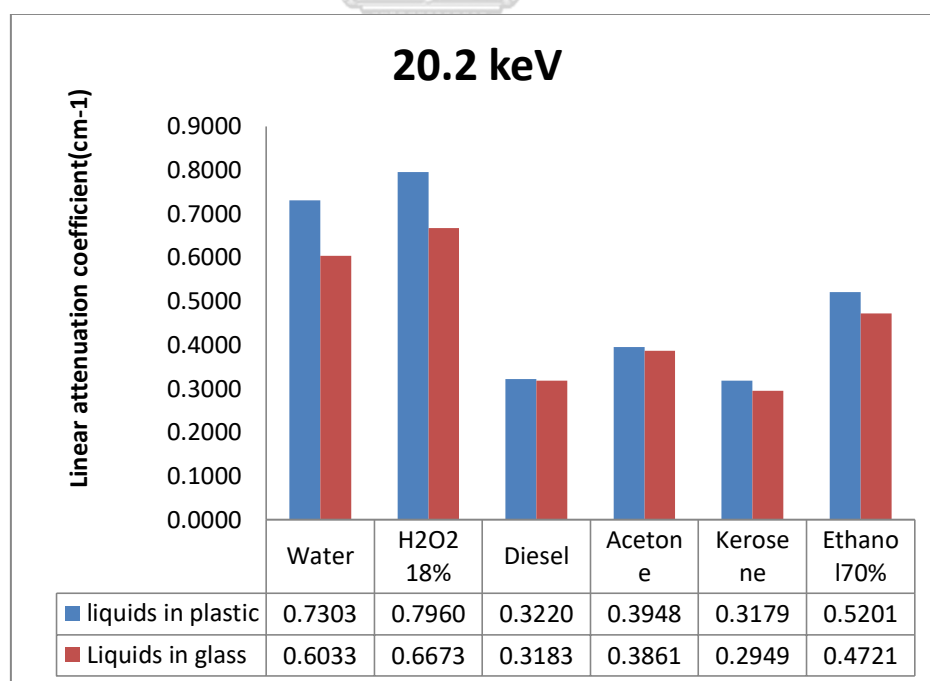

Figure 4.9 The linear attenuation of liquids in glass and plastic bottles at 20.2 keV.

Figure 4.10 The linear attenuation of liquids in glass and plastic bottles at 43.5 keV.

Most of the cans are fully filled with liquids, so the thickness of aluminum and steel cans must be estimated from the obtained linear attenuation coefficient of cans and the thickness of 0.01 cm for aluminum and 0.02 for steel cans.

Some kinds of liquids contained in metal cans were tested for determination of the linear attenuation coefficients including water, soft drink, hydrogen peroxide, coffee, milk, diesel oil, acetone, alcohol, and kerosene. The results are shown in Table 4.29.

Table 4.29 Average linear attenuation coefficients ( $\text{cm}^{-1}$ ) of liquids contained in metal cans

Type of liquids	Average linear attenuation coefficient ( $\text{cm}^{-1}$ )				
	13.6 keV	17.2 keV	20.1 keV	43.5 keV	
Softdrink	I <sub>x</sub> is too low for calculation	1.1310±0.0094	0.7356±0.0027	0.2362±0.0081	
Water		1.1036±0.0046	0.7206±0.0030	0.2295±0.0046

Table 4.29(continue) Average linear attenuation coefficients ( $\text{cm}^{-1}$ ) of liquids contained in metal cans

Type of liquids	Average linear attenuation coefficient ( $\text{cm}^{-1}$ )			
	13.6 keV	17.2 keV	20.1 keV	43.5 keV
Milk	$I_x$ is too low for calculation			$0.2365 \pm 0.0064$
Diesel	$0.7442 \pm 0.0027$	$0.4428 \pm 0.0008$	$0.3214 \pm 0.0011$	$0.1778 \pm 0.0042$
Acetone	$1.0141 \pm 0.0055$	$0.5603 \pm 0.0011$	$0.3866 \pm 0.0013$	$0.1802 \pm 0.0042$
Ethanol70%	$1.5598 \pm 0.0231$	$0.7649 \pm 0.0019$	$0.5084 \pm 0.0018$	$0.2045 \pm 0.0044$
Kerosene	$0.6979 \pm 0.0024$	$0.4170 \pm 0.0008$	$0.3032 \pm 0.0011$	$0.1632 \pm 0.0041$

The results show that linear attenuation coefficients of liquids in cans had the same trend from plastic and glass bottle. Steel cans have high linear attenuation coefficient so that transmitted intensity ( $I_x$ ) was too low to calculate at low energy (13.6-20.1 keV). The linear attenuation coefficients of coffee and milk in steel cans could be determined using the 43.5 keV gamma-ray peak.

There are two types of can including aluminum cans and steel cans. The average linear attenuation coefficient of aluminum cans at 20.1 keV is  $9.6949 \pm 0.4472 \text{ cm}^{-1}$  while that of steel cans is as high as  $145.2940 \pm 2.7782 \text{ cm}^{-1}$ . Nevertheless, the thickness of aluminum and steel cans were found to be about the same at 0.01 cm and 0.02 cm respectively. Thus, attenuation correction of x-rays by aluminum and steel cans can be easily calculated by using the obtained linear attenuation coefficients and these thicknesses.

#### 4.4.2 Result of bottle without air gap inside

Commercial liquid contained in cans were tested including drinking water, orange juice, milk, green tea, and coffee. The estimated thickness of PET plastic, HDPE plastic, aluminum can and steel can were 0.02, 0.05, 0.01 and 0.02 cm respectively whereas thickness of glass bottle were be obtained by ultrasonic thickness gauge. The results are shown in the tables below.

Table 4.30 The calculated  $I_0$  obtained from the estimated thickness of the plastic bottles

	Estimate thickness (cm) (2 sides)	Intensity at each energy			
		13.6 keV	17.2 keV	20.1 keV	43.5 keV
$I_{\text{air}}$	-	184615	324206	83434	2959
$I_0$ HDPE <sub>milk</sub>	0.1	165566	307369	80341	2959*
$I_0$ PET	0.04	168144	309352	81718	2959*
$I_0$ HDPE <sub>Shampoo</sub>	0.1	157003	296883	79477	2959*
$I_0$ Can	0.02	99465	237575	68027	2898

\* $\mu$  of plastic at 43.5 keV is very low thus  $I_0$  is approximately  $I_{\text{air}}$

Table 4.31 The calculated  $I_0$  obtained from the estimated thickness of the glass bottles

	Estimate thickness (cm) (2 sides)	Intensity at each energy			
		13.6 keV	17.2 keV	20.1 keV	43.5 keV
$I_0$ Soy milk Glass	0.400 (UT)	$I_x$ is too low for calculation	4468	7760	3607

The results show that liquids in commercial bottles can be classified by using low energy x-ray transmission technique. Most of the commercial bottles have diameter ranging about 4-6 cm, so x-ray energy 13.6 keV cannot penetrate through the bottle and liquid. The appropriate x-ray energy in this technique is 17.2 keV but when the bottle diameter higher, the higher x-ray energy can be used.

Figure 4.11 Linear attenuation coefficient of liquids at each energy.

Table 4.34 Summary of the linear attenuation coefficients of liquids at each energy

## Discussion

The x-ray energy that suitable for low energy x-ray transmission technique is depending on the bottle diameter. The 13.6 keV x-ray give excellent results to distinguish kind of liquid but its penetrating power is limited to about 3 cm. Multi-energy source like  $^{238}\text{Pu}$  is very useful for larger diameter bottles because 17.6 keV and 20.1 keV x-rays as well as 43.5 keV gamma-ray can be utilized. But the intensity of the 20.1 keV-x-ray and the 43.5 keV-gamma-ray are too low for short counting time. For a larger bottle,  $^{238}\text{Pu}$  may be replaced by  $^{241}\text{Am}$  source which emits Np L x-rays nearly the same energies as those of  $^{238}\text{Pu}$  as can be seen in table 2.1. Very importantly, the source window has to be made of thin beryllium (Be) window to allow Np L x-rays to come out. Moreover,  $^{241}\text{Am}$  also emits 59.5 keV gamma-ray at much higher percentage ( $\sim 36\%$ ) and 26.3 keV gamma-ray (2.5%) in comparison to 43.5 keV ( $\sim 0.4\%$ ) of  $^{238}\text{Pu}$ . The source activity is a major factor that affect the counting time. Only about 10 mCi or 0.37 GBq  $^{238}\text{Pu}$  is used in this research which seems to be very low. The activity should be increased to 100 mCi (3.7 GBq) or more to shorten the counting time.

The detector is another important factor. The 5 mm x 5 mm CdTe detector used in this experiment is very small but it gives very good energy resolution with relatively low detection efficiency. All major peaks can be observed separately. Larger CdTe detectors are now available for higher detection efficiency. A low energy high purity germanium detector with Be window gives much higher detection efficiency with better energy resolution But its size, cooling system and cost may not be appropriate for a compact system. A gas proportional detector may be another choice of detector. It gives poorer energy resolution but may be enough for this purpose. All three energy peaks from  $^{238}\text{Pu}$  x-rays are not completely resolved. Integration of all three peaks together may be applicable for this purpose. The only drawback is its detector efficiency drops rapidly beyond about 30 keV.

It will be better to have two sets of source-detector for inspection the bottle at 2 positions such as at the liquid portion and at the empty portion.

For fixed liquid thickness at 4.5 cm, uncertainty of the measurement is caused by curvature of the container as shown in figure 4.12 and figure 4.13. This error can be solved by applying a correction factor which can be obtained from experiment or calculation. If the x-ray beam is narrower, this error should be reduced.

Figure 4.12 Photon through the liquid for a large bottle diameter.

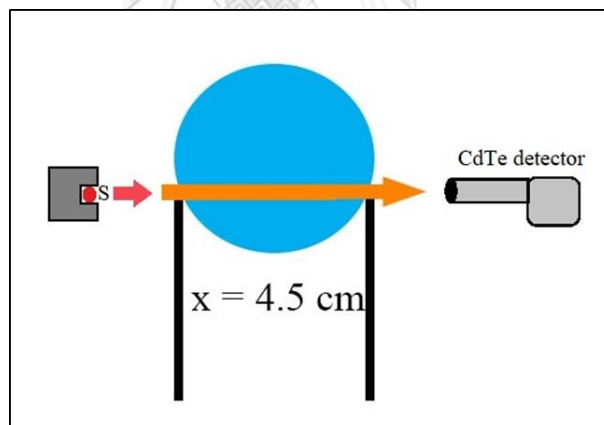

Figure 4.13 Photon through the liquid for a small bottle diameter.

Thickness of the plastic bottle can be estimated due to linear attenuation coefficient of plastic is very low. In contrast with glass and can, the linear attenuation coefficient of glass and can are very high but can is a thin bottle and the thickness of can is the same all of the bottle so that the thickness of can may be estimated by 0.01 cm for aluminum and 0.02 cm for steel can.

The thickness of glass bottle is not the same at different position due to its production process. Estimation of thickness can cause large error. The thickness of glass has to be measured by the ultrasonic thickness gauge at the same position with the x-ray transmission technique.

Conceptual design of the prototype equipment to be used for screening of liquid in unopened bottles at airports is shown in Figure 4.14 and Figure 4.15.

Figure 4. 14 Diagram of the prototype equipment to be used for screening of liquid in unopened bottle at airports (Side view) มหาวิทยาลัย

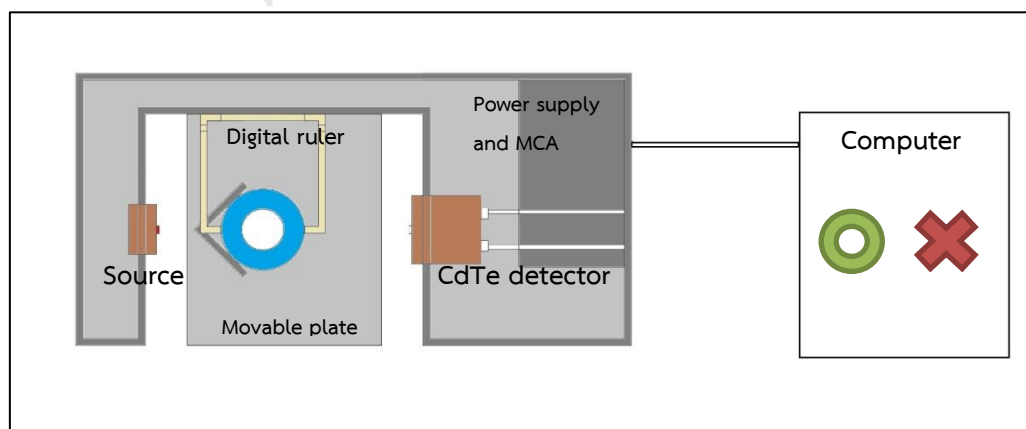

Figure 4.15 Diagram of the prototype equipment to be used for screening of liquid in unopened bottle at airports (Top view)

Radioisotope source and detector are positioned on the opposite side of the bottle under inspection. The movable plate at the bottom can be moved up and down to measure incident and transmitted intensity at a desired position. The bottle diameter is measured by a digital ruler that installed behind the bottle under inspection. The bottle can be centered by the angle plate that mounted with the movable plate at the bottom. The detector is connected to a power supply and a digital spectrum analyzer which is connected to a computer to display spectrum, perform spectrum analysis, report analysis results and any other functions to assist the operator. A data base system for bottle type, linear attenuation coefficients of liquids, bottle thickness and materials are included in the computer system.

## CHAPTER V

### CONCLUSION

The proposed technique is simple but can distinguish kinds of liquid efficiently. The separation factors between different kinds of liquid are very high. The technique can even distinguish differences in concentration of the same substance such as percentage of ethanol, kinds of fuel oil, etc. For example, the linear attenuation coefficients of benzene 95, gasohol 95 (10% ethanol), gasohol E20 (20% ethanol), gasohol E85 (85% ethanol) and ethanol (95%) at 13.6 keV x-rays are about 0.6660, 0.7036, 0.7793, 1.0279 and 1.2112  $\text{cm}^{-1}$  respectively. These increases in the linear attenuation coefficients are caused by increase in percentage of ethanol from 0 to 95 %. The multiple x-rays energy gives choices to select appropriate energy peaks to be used for screening in single measurement. The only thing that still needs further investigation is to collect data related to bottle and bottled liquid. Bottle types, bottle material and bottle thickness are different from country to country. In addition, information on bottled liquids, deleterious liquid and liquid explosive are also of great importance for screening.

In this research, the bottles are divided into 3 groups i.e. plastic bottles, glass bottles and metal cans. Plastic bottles are made of PET, PE and HDPE whose linear attenuation coefficients are not high and are in the same range as liquid. PET bottles are thin such as water, soft drink and fruit juice bottles are about 0.01 – 0.02 cm thick. PE or HDPE bottles such as milk, dairy products, fruit juice are about 0.04 – 0.07 cm thick. Measurement of  $I_0$  is preferable when there is air portion in transparent bottles. For opaque bottle like HDPE and PE, scanning for air portion is actually possible but it will take time. Thus, the average linear attenuation coefficient of the HDPE bottles is used together with the estimated thickness to calculate  $I_0$ . This method is also applied for aluminum and steel cans. For glass bottles, the average linear attenuation coefficient of glass bottles is used together with the bottle thickness measured by the ultrasonic thickness gauge. However,

transparent bottles (such as beer, wine and fruit juice) can actually be measured by x-ray transmission at the air portion but non-uniform thickness of glass may cause large error.

Table 5.1 Conclusion of procedure for determining the linear attenuation coefficients of bottled liquid

Bottle type	Method to obtain $I_0$
Plastic - PET (with air portion) - PET (without air portion) - HDPE (opaque)	- X-ray transmission at the air portion - Calculated from $\mu$ and the estimated bottle thickness of 0.02 cm - Calculated from $\mu$ and the estimated bottle thickness 0.05 cm
Glass - Glass (with air portion) - Glass (without air portion)	- X-ray transmission at the air portion - Calculated from $\mu$ and the bottle thickness obtained from ultrasonic thickness gauge
Metal Cans - Aluminum (opaque) - Steel (opaque)	- Calculated from $\mu$ and the estimated bottle thickness of 0.01 cm - Calculated from $\mu$ and the estimated bottle thickness of 0.02 cm

The equipment for use in liquid screening at airports should be compact, easy to operate and reliable. Sensitivity of the proposed technique is obviously good but to bring it to routine inspection is still a big challenge. A data base of bottle types and liquids should be carefully developed to assist in screening the bottled liquid. Further investigation related to bottle type and bottled liquids should be conducted to collect more information to be used in screening of unwanted and deleterious liquids.

## VITA

Name: Parkphum Orachorn

Date of birth: 22 November 1984

Education: Bachelor of Science (Physics) Khonkaen University 2002-2005

Master of Science(Nuclear Technology) Chulalongkorn University 2006-2009

Address: 179/3 moo9 Chongsammor Kaengkro Chaiyaphum Thailand 36150

Scholarship: Development and Promotion of Science and Technology Talents Project (DPST)
