## APPENDICES

### Appendix A Identification of FT-IR Spectrum

#### Synthesized polydiphenylamine (PDPA) and dedoped Polydiphenylamine

Polydiphenylamine (PDPA) was synthesized via the oxidative polymerization of diphenylamine(DPA) to obtain doped-PDPA (D\_PDPA) (Orlov *et al.*, 2005). The PDPA was dedoped by immersing in ammonium hydroxide solution to become neutral PDPA (De\_PDPA). The polymers were first characterized for the functional groups by a FT-IR spectrometer (Thermo Nicolet, Nexus 670) in absorption mode with 32 scans and a resolution of  $\pm 4 \text{ cm}^{-1}$ , wavenumbers range of  $4000\text{-}400 \text{ cm}^{-1}$ , and using a deuterated triglycine sulfate as a detector. Optical grade KBr (Carlo Erba Reagent) was used as the background material. De\_PDPA and D\_PDPA were intimately mixed with dried KBr at a ratio of PDPA: KBr = 1:20.

**Figure A1** The FT-IR spectrum of doped-Polydiphenylamine (D\_PDPA) and dedoped\_polydiphenylamine (De\_PDPA).

**Table A1** The FT-IR absorption spectrum of D\_PDPA and De\_PDPA

*Variation of doping mole ratio ( $N_{HCl}/N_{monomer}$ ) of PDPA*

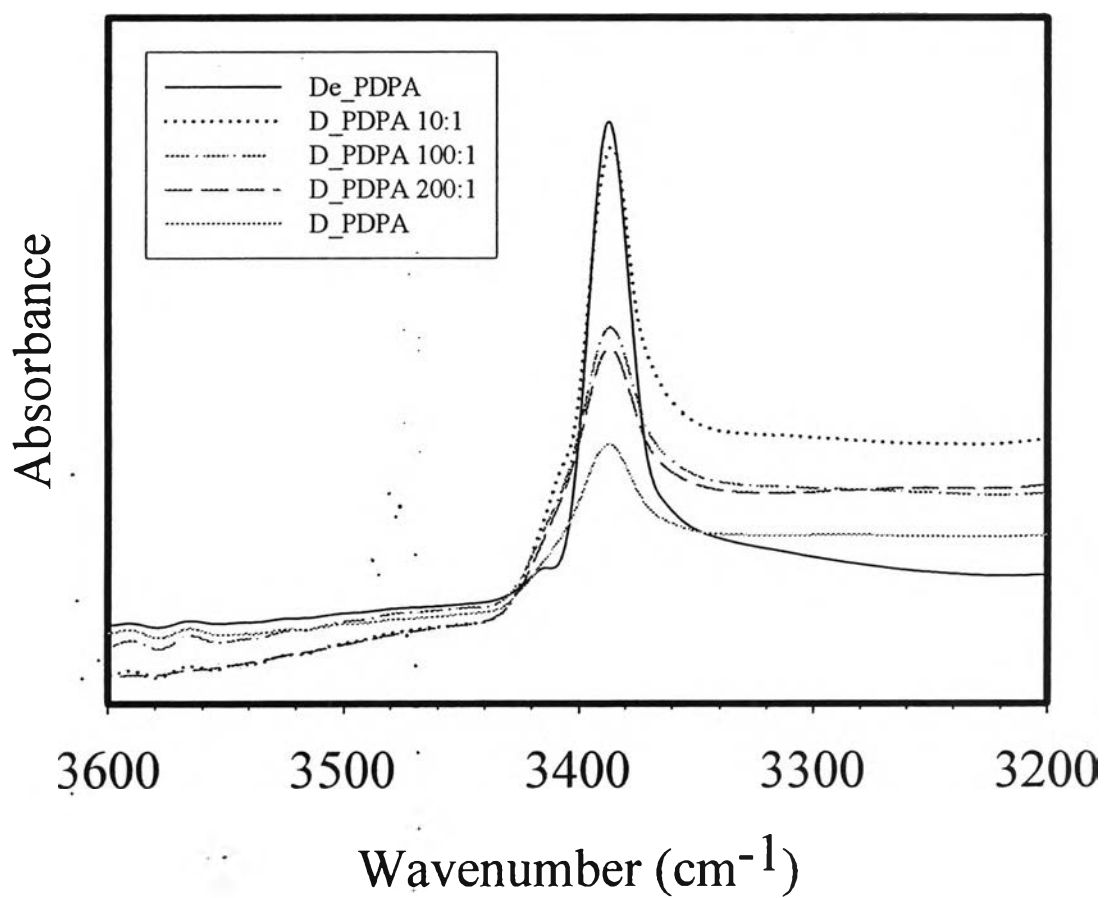

The dedope-PDPAr was doped with HCl at various doping mole ratio ( $N_{HCl}/N_{monomer}$ ). The mole ratios chosen were 1:100, 1:10, 1:1, 10:1, 100:1, and 200:1. The dedoped-PDPA powder was stirred with HCl solutions for 24 hrs, filtered, and vacuum dried at 25°C for 24 hrs. To compare peaks intensity of FT-IR spectra of De\_PDPA and D\_PDPA of various doping mole ratios PDPA 10:1, 100:1, 200:1, and synthesized PDPA in 1 M HCl. 0.76 mg of each polymer was precisely mixed with 51.4 mg of dried-KBr, or 3:200 (g/g), the mixed samples were compressed into sample pellets. The FT-IR spectrum of each polymer is compared to each others as in the following (Figure A2).

**Figure A2** FT-IR spectra of dedoped-Polydiphenylamine (De\_PDPA) and doped\_Polydiphenylamine (D\_PDPA) of various doping levels 10:1, 100:1, 200:1, and the synthesized PDPA in 1 M HCl.

The spectra show above the N-H stretching peaks at 3400 cm<sup>-1</sup> (Zhao *et al.*, 2005); the peak intensity significantly decreases as the doping mole ratio is increased (Figure A3). Moreover, in the range of 2000 cm<sup>-1</sup> to 3800 cm<sup>-1</sup>, the spectra of the doped PDPA become broad peaks while the spectrum of dedoped PDPA becomes shape and planar peak.

**Figure A3** FT-IR spectra of dedoped-Polydiphenylamine (De\_PDPA) and doped\_Polydiphenylamine (D\_PDPA) of various doping level 10:1, 100:1, 200:1, and the synthesized PDPA in 1 M HCl, at wavenumber between 3200-3600 cm<sup>-1</sup>.

## Appendix B Identification of Characteristic Peaks of Dedoped and Doped Poly(diphenylamine) from UV-Visible Spectroscopy

UV-Vis spectra were recorded with a UV-Vis absorption spectrometer (Perkin-Elmer, Lambda 10). Measurements were taken in the absorbance mode in the wavelength range of 200-900 nm. Doped-PDPAs were prepared by stirring the polymers powder with HCl solutions for 24 hours using various mole ratio of HCl to PDPA monomer (100:1 10:1 1:1 1:10 and 1:100). Dedoped-PDPA was dissolved in THF at the concentration of 0.05 g/L. Scan speed is 240 mm/min, and a slit width of 2.0 nm, using a deuterium lamp as the light source.

(b)

**Figure B1** UV-Visible spectra of Dedoped-poly(diphenylamine)(De\_PDPA) and HCl-doped poly(diphenylamine)(D\_PDPA) at the mole ratio of acid to monomer of 100:1, 10:1, 1:1, 1:10 and 1:100 in THF : (a) the significant peak at wavelength about 320 nm for the Benzenoid ring; (b) the peaks at wavelength about 520nm indicating the neutralized amine.

**Table B1** Absorbance spectra of Dedoped-poly(diphenylamine)(De\_PDPA) and HCl-doped-poly(diphenylamine)(D\_PDPA) at the mole ratio of acid to monomer 100:1, 10:1, 1:1, 1:10 and 1:100, in THF

### Appendix C The Thermogravimetry Analysis of dedoped-polydiphenylamine (De\_PDPA)

The thermogravimetric analyzer (Perkin Elmer, TGA7) was used to determine the thermal behavior of polymers. The experiment was carried out by weighting a powder sample of 5-10 mg and placed it in a platinum pan, and then heated it under nitrogen flow with the heating rate 10 °C/min from 30-800°C. From Figure C1, the TGA thermogram of De\_PDPA indicates degradation of De\_PDPA main chain beyond the temperature of 440°C.

Figure C1 TGA thermogram of De\_PDPA.

## Appendix E Correction Factor (K) Measurement

A two point probe meter connected with a source power supplier (Keithley/ Model 6517A) was employed to determine the electrical conductivity of materials. A constant voltage was applied and the current was simultaneously measured.

According to the geometric effects of the probe, the geometrical correction factor depends on the configuration and probe tip spacing:

$$K = w/l \quad (\text{E.1})$$

where  $K$  is the geometric correction factor,  $w$  is the probe width or the tip spacing (cm), and  $l$  is the probe length (cm).

The geometric correction factor can be determined by using standard materials whose specific resistivity values are known. In our case, silicon wafer chips were used as the standard materials. The resistance was measured by using our custom-made two-point probe, obtained by applying various voltages and simultaneously measuring currents. The geometric correction factor was calculated via the equation:

$$K = \rho/R \times t = I \times \rho/V \times t \quad (\text{E.2})$$

where  $\rho$  is the resistivity of a standard silicon wafer ( $\Omega \cdot \text{cm}$ ),  $R$  is the resistance of film ( $\Omega$ ),  $t$  is the film thickness (cm),  $I$  is the measured current (A) and  $V$  is the applied voltage (V).

**Table E1** Voltage-current data of the probe number 1 calibration with Si-wafer whose sheet resistivity of 107.373  $\Omega/\text{sq}$ , 25°C, 60-65 %RH

## Appendix F Conductivity Measurement

The electrical conductivity ( $\sigma$ ) can be measured by using the two-point probe meter connected with a voltage supplier (Keithley, 6517A) whose constant voltage can be varied and the current is measured. The conductivity measurement was performed under atmospheric pressure, 40-60 %RH and at 25-27°C. The regime where responsive current is linearly proportional to the applied voltage is called the linear Ohmic regime which can be identified by plotting the applied voltage against with the current. The voltage and the current in the regime were converted to the electrical conductivity by following equation:

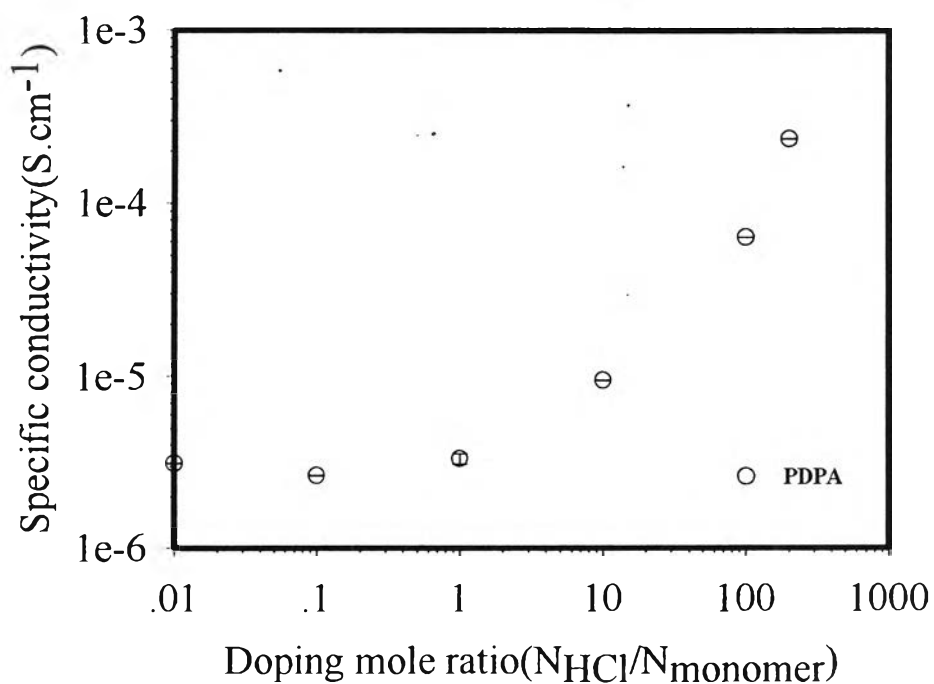

$$\sigma = I/\rho = I/(R \times t) = I/(R_s \times V \times t) \quad (\text{F.1})$$

where  $\sigma$  is the specific conductivity (S/cm),  $\rho$  is the specific resistivity ( $\Omega \cdot \text{cm}$ ),  $R_s$  is the sheet resistance ( $\Omega/\text{sq}$ ),  $t$  is the thickness of sample pellet (cm),  $V$  is the applied voltage (Voltage drop)(V),  $I$  is the measured current (A), and  $K$  is the geometric correction factor of the two-point probe meter. All sample thicknesses were measured by using a thickness gauge.

**Table F1** The specific conductivity (S/cm) of De\_PDPA, D\_PDPA with various doping levels, SIS D1114, SIS D1164, and SIS D1162

Samples	Specific conductivity(S/cm)
De PDPA	$(2.89 \pm 0.315) \times 10^{-6}$
D PDPA200:1	$(2.35 \pm 0.214) \times 10^{-4}$
D PDPA100:1	$(6.31 \pm 0.234) \times 10^{-5}$
D PDPA10:1	$(9.46 \pm 0.349) \times 10^{-6}$
D PDPA1:1	$(3.32 \pm 0.229) \times 10^{-6}$
D PDPA1:10	$(2.65 \pm 0.118) \times 10^{-6}$
D PDPA1:100	$(3.13 \pm 0.167) \times 10^{-6}$
SIS D1114	$(1.28 \pm 0.158) \times 10^{-19}$
SIS D1164	$(2.69 \pm 0.326) \times 10^{-17}$
SIS D1162	$(1.17 \pm 0.100) \times 10^{-17}$
5% De PDPA/D1114P	$(2.24 \pm 0.106) \times 10^{-16}$
10% DePDPA/D1114P	$(2.65 \pm 0.141) \times 10^{-15}$
20% DePDPA/D1114P	$(2.25 \pm 0.536) \times 10^{-14}$
30% DePDPA/D1114P	$(4.80 \pm 0.830) \times 10^{-14}$

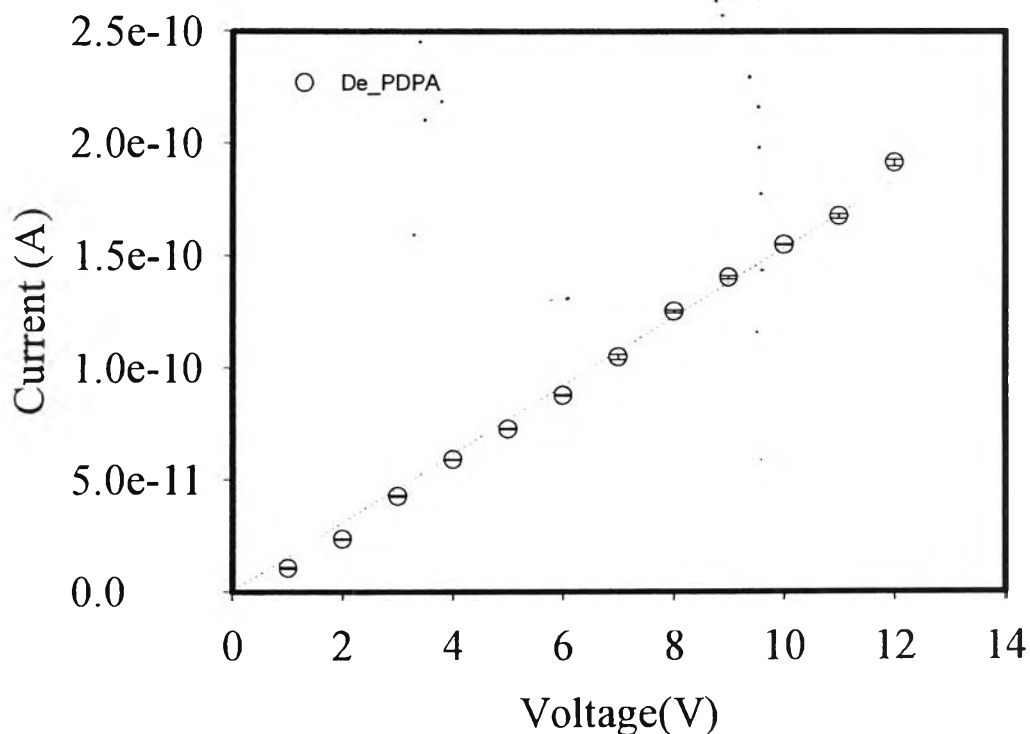

Polydiphenylamine

## Appendix H Electrorheological Properties Measurement

### Temporal response: pure SIS film by using stretch fixture

The temporal response of pure SIS films with different morphology; D1114P; D1164P; and D1162P were investigated by the rheometer (Rheometric Scientific, ARES). It was fitted with a custom-built stretch fixture, gap = 30 mm. A DC voltage was applied with a DC power supply (Gold Sun 3000, GPS 3003D) work with high voltage power supply (Gamma High Voltage, UC5-30P), which can deliver electric field strength up to 1 kV/mm. A digital multimeter was used to monitor the voltage input. In the temporal response testing, the dynamic strain was applied and the dynamic moduli ( $G'$  and  $G''$ ) were measured as functions of time and electric field strength. Dynamic strain sweep test were first carried out to determine suitable strains to measured  $G'$  and  $G''$  in linear viscoelastic regime, as following figures (Figure H1, H2, and H3). The appropriate strains were determined to be 0.2 % for the pure films.

**Table H1** Storage modulus and loss modulus data, obtained from dynamic strain sweep test of D1114P (19%wt PS), stretch fixture, gap = 30 mm, film thickness = 0.296 mm, film width = 7.0mm, electric field ( $E$ ) = 0 V/mm, 25°C

**Figure H3** Storage modulus and loss modulus versus strain (%) obtained from dynamic strain sweep test of D1162P (44%wt PS), stretch fixture, gap = 30 mm, film thickness = 0.351 mm, film width = 6.5 mm, electric field (E) = 0 V/mm, 25°C.

The time sweep test was carried out with electric field applied on and off, alternatively. The G' of each film was investigated to measure time that each film response reach to steady state and there response under electric field stimulation. Figure H4 shows G' of D1114P was steady state after 2600 s of measurement. Moreover, the film is not affected stimulated by electric field (1 kV/mm), it is stress free system. In the case of, Figure H5 and H6, D1164P and D1162P were steady state after 4200 s and 2600 s, respectively. There also shows the similar response under electric field as the D1114P film.

**Figure H4** Temporal response testing of storage modulus ( $G'$ ) of D1114P (19 %wt PS), stretch fixture, strain 0.2 %, gap 30 mm, film thickness 0.296 mm, film width 7.0 mm, frequency 1.0 rad/s, electric field ( $E$ ) 1 kV/mm, 25°C.

**Figure H5** Temporal response testing of storage modulus ( $G'$ ) of D1164P (29 %wt PS), stretch fixture, strain 0.2 %, gap 30 mm, film thickness 0.429 mm, film width 7.0 mm, frequency 1.0 rad/s, electric field ( $E$ ) 1 kV/mm, 25°C.

**Figure H6** Temporal response testing of storage modulus of D1162P (44 %wt PS), stretch fixture, strain 0.2 %, gap 30 mm, film thickness 0.351 mm, film width 6.5 mm, frequency 1.0 rad/s, electric field (E) 1 kV/mm, 25°C.

Temporal response: pure SIS film by using parallel plates

The temporal response of pure SIS films with different morphology; D1114P; D1164P; and D1162P were carried out by melt rheometer meter (Rheometric Scientific, ARES). It was fitted with a custom-built copper parallel plates fixture, diameter 25 mm. A DC voltage was applied by DC power supply (Instek, GFG 8216A), which can deliver electric field strength to 2 kV/mm. A digital multimeter was used to monitor the voltage input. For temporal responses testing, oscillate shear strain was applied and the dynamic moduli ( $G'$  and  $G''$ ) were investigated as a function of time and electric field strength. Dynamic strain sweep test were first carried out to determine appropriate strains by measured  $G'$  and  $G''$  in linear viscoelastic regime. The following figures, Figure H7, H9, and H11, show linear viscoelastic regimes of pure SIS films: D1114P; D1164P; and D1162P; respectively, without electric field strength (0 V/mm). Besides, Figure H8, H10, and H12, show

the linear viscoelastic regimes of pure SIS films in the influence of electric field strength at 2 kV/mm.

**Figure H12** Storage modulus and loss modulus versus strain (%) obtained from dynamic strain sweep test of D1162P (44 %wt PS), parallel plate, gap = 0.861 mm, film diameter = 25 mm, electric field (E) = 2 kV/mm, 27°C.

The time sweep test was carried out with electric field applied on and off, alternately. The  $G'$  of each film was investigated to measure the time each film response reaches a steady state and there is no response under electric field stimulation. In Figure H13, the dynamic storage modulus ( $G'$ ) of D1114P was in steady state after 1000 s of measurement, without electric field strength. After that, the electric field was alternately applied. From the figure, D1114P could not be stimulated by electric field at 2 kV/mm. Similar result to D1114P, pure SIS D1164P reached a steady state after 1000 s of measurement in absence of electric field. But the film modulus ( $G'$ ) is not response to the electric field. In the case of D1162P which reached a steady state after 1200 s, its response was similar to the first two, D1114P and D1164P. Their behaviors depend on their dielectric constant. Because they are low dielectric materials. Thus, the force generated under electric field is low. The effective actuation force is given by (Pelrine *et al.*, 2000):

$$p = \epsilon\epsilon_0 E^2 = \epsilon\epsilon_0 (V/z)^2 \quad (\text{H.1})$$

where  $p$  is the actuation pressure,  $E$  is the electric field strength,  $\epsilon$  is the dielectric constant,  $\epsilon_0$  is the permittivity of free space,  $V$  is voltage, and  $z$  is the polymer thickness.

**Figure H13** Temporal response testing of storage modulus ( $G'$ ) of D1114P (19 %wt PS), parallel plate, strain 0.2 %, gap 0.997 mm, film diameter 25 mm, frequency 1.0 rad/s, electric field (E) 2 kV/mm, 27°C.

**Figure H14** Temporal response testing of storage modulus ( $G'$ ) of D1164P (29 %wt PS), parallel plate, strain 0.1 %, gap 1.058 mm, film diameter 25 mm, frequency 1.0 rad/s, electric field (E) 2 kV/mm, 27°C.

## Appendix I Density Determination by Pycnometer

The density of dedoped-Polydiphenylamine and the doped-polymers with various doping mole ratios was determined by using Ultrapycnometer (Ultrapycnometer 1000, V 2.4) with small cell size. The polymers were firstly vacuum-dried for 24 hr and then weighted at ambient temperature, loaded the sample to the cell. Density determination was carried out 10 time for each sample for a run under flow purge mode, target gas pressure 17 psi, and calibration volumes:  $V_{\text{added}}$  12.4159 cm<sup>3</sup>;  $V_{\text{cell}}$  20.8093 cm<sup>3</sup>.

## Appendix K Analysis of deflection force of pure SIS films

Deflection of SIS films; D1114P (19%wt PS), D1164P (29%wt PS), and D1162P were carried out under various applied-electric strengths. For each of SIS films, one end of the sample was fixed with tong vertically in the chamber, which consisted of two electrodes and poly(dimethylsiloxane). The input DC field was generated by a DC power supply (Gold Sun 3000, GPS 3003D) and a high voltage power supply (Gamma High Voltage, UC5-30P) which delivered to the electrodes various electric fields (25, 50, 75, 100, 125, 150, 175, 200, 225, 250, 275, 300, 325, 350, 375, 400, 425, 450, 475, 500, 525, 550, 575, and 600 V/mm). A video recorder was used to record the displacement of the film made a model. The tip displacement was measured through a Scion Image (Beta 4.0.3) program.

To calculate the theoretical force of sample displacement it can be regarded as a cantilever beam. It is assumed that the sample is symmetric with respect to the longitudinal direction and that a concentrated load is acting at the tip of an actuator. Then, the relation between tip displacements ( $d$ ) and force ( $Fe$ ) are calculate from the linear deflection and non-linear deflection models depending on their bending characteristic (Figure K1), as the following:

$$\text{(Linear deflection)} \quad Fe = \frac{3dEI}{l^3} \quad (\text{K.1})$$

$$\text{(Non-linear deflection)} \quad Fe = \frac{dEI}{l^3} \quad (\text{K.2})$$

where  $E$  is the modulus of elasticity (Pa),  $d$  is displacement distance in x axis (mm),  $I$  is the moment of inertia ( $\text{m}^4$ ), and  $l$  is the deflection distance in y axis (mm), which are shown in Figure K1.

**Figure K1** deflection of one free end sample beam.

**Figure K2** (a) Linear deflection and (b) Non-linear deflection of the sample under electric field.

But, the absolute vertical deflection force at the free end of the sample does not only depend on Elastic force ( $F_e$ ), but also depend on weight in deflection direction, ( $mg \sin(\theta)$ ). Thus, the absolute deflection force of free end of sample beam or dielectrophoretic force is the sum of the elastic force ( $F_e$ ) and  $mg \sin(\theta)$ , as in the following equation:

$$\text{(Dielectrophoretic force)} \quad Fd = F_e + mg \sin \theta \quad (\text{K.3})$$

## CURRICULUM VITAE

**Name:** Mr. Kraipop Thongsak

**Date of Birth:** September 29, 1984

**Nationality:** Thai

**University Education:**

2002-2006 Bachelor Degree of Engineering, Faculty of Engineering and Industrial technology, Silpakorn University, Nakornpathom, Thailand

**Proceedings:**

1. Thongsak, K., Sirivat, A., and Lerdwijitjarud, W. (2008, April 23). Electroactive Polydiphenylamine/Styrene-Isoprene-Styrene (SIS) blends in the effect of morphology and particle concentration Proceedings of the 14<sup>th</sup> PPC Symposium on Petroleum, Petrochemicals, and Polymers, Bangkok, Thailand.
