APPENDIX A

FT-IR Spectrum of Emeradine Base and Doped Polyaniline

The polyaniline was first characterised by FT-IR spectroscopy in order to identify functional groups. Ten-mg sample was grounded and mixed with 50-mg KBr. The FT-IR spectrum was observed by using an FT-IR spectrometer (Bruker, model EQUINOX55/S) with the absorption mode 32 scans at the resolution of 4cm^{-1} .

Figure A1 The FT-IR spectrum of PANI doped with HCl, MA, and CSA with $N_A/N_{EB} = 10$.

APPENDIX B

TGA Thermogram of Emeradine Base and Doped Polyaniline

The thermogravimetric analyzer (DuPont, model TGA 2950) was used to determine the amount of moisture content, and dopant in each sample. The experiment was carried out by weighting powder sample of 10-15 mg and placed it in an aluminum pan, and then heated it under a nitrogen gas flow with the heating rate 10 °C / min from room temperature to 700 °C. Two transitions were observed in each sample, 110-130 °C and 130-400 °C; they refer to the losses of water and dopant, respectively. The degradation temperature of polyaniline appears at 640-670 °C.

APPENDIX C

Percent Doping Level of Doped Polyaniline Using FT-IR Measurement

The percent doping level of polyaniline can be calculated from the amount of C=C from benzenoid part and the –N= of quinoid part, which was observed from FT-IR spectrum at the wave numbers of 1450 cm⁻¹ and 1557 cm⁻¹ respectively. The absorbency of each peak was calculated according to Beer's Lambert equation;

$$\text{Beer's law} \quad A = \epsilon bc \quad (\text{C.1})$$

where A is the area of each peak
 ϵ is the absorptivity (cm²/g)
 b is path length (cm)
 c is the concentration of sample (g/cm³)

The doping ratio of polyaniline can be written following the Beer's law

$$\frac{C_{(C=C)}}{C_{(-N=)}} = \frac{A_{(C=C)}}{A_{(-N=)}} \cdot \frac{\epsilon_{(-N=)}}{\epsilon_{(C=C)}} \cdot \frac{b_{(-N=)}}{b_{(C=C)}} \quad (\text{C.2})$$

By considering the structure of polyaniline, the values of $\frac{C_{(C=C)}}{C_{(-N=)}}$ of fully doped polyaniline and emeraldine base are supposed to be equal to 12 and 5.5 respectively. The term $\frac{\epsilon_{(-N=)}}{\epsilon_{(C=C)}} \cdot \frac{b_{(-N=)}}{b_{(C=C)}}$ is constant with the same dopant type, which is equal to r . The constant (r) was obtained from the experiment, which are 0.34, 0.20, and 0.18 for PANI doped with HCl, MA, and CSA respectively.

The area of absorption peak was determined by using Gaussian equation.

$$\text{Gaussian equation} = (1/(SD*((2*(22/7))^{0.5}))) * \exp(0.5(((x-avg)/SD)^2)) * \text{area} \quad (\text{C.3})$$

Finally, the percent doping level of doped polyaniline was calculated by this equation.

$$\% \text{ doping level} = \frac{((A_{(C=C)}/A_{(-N=)}) r) - 5.5}{12 - 5.5} 100 \quad (\text{C.4})$$

Table C1 Summary of the percent doping level of PANI-HCl, PANI-MA, and PANI-CSA

Sample	Absorption		$A_{(C=C)}/A_{(-N=)}$	% doping level
	$A_{(C=C),1480}$	$A_{(-N=),1557}$		
EB	33.92	66.08	0.51	0.55
1HCl	73.96	26.04	2.84	42.95
10HCl	80.43	19.57	4.11	100.00
1MA	69.53	30.47	2.28	86.70
10MA	71.09	28.91	2.46	100.00
1CSA	65.88	34.12	1.93	77.34
10CSA	68.76	31.24	2.20	100.00

APPENDIX D

Calculation of Doping Level Using Elemental Analysis

The elemental analyzer was used to determine the percents of carbon (%C), hydrogen (%H) and nitrogen (%N) in PANI and doped PANI. The percent doping level was calculated from the ratio of acid per nitrogen in sample. From the weight loss of water from TGA data, the amount of oxygen in PANI sample can be calculated.

$$\% O_{\text{water}} = \frac{\% \text{ weight lost of water from TGA} \times 16 \text{ g of O/ mol}}{18 \text{ g H}_2\text{O/ mol}} \quad (\text{D.1})$$

In addition, the amount of the remaining oxidant has to be subtracted for each sample, before calculating the percent doping level. The calculation of the percent of doping level of emeraldine base is by the following equation:

$$\% \text{ Residue oxidant} = 100 - (\%C + \%H + \%N + \% O_{\text{water}}) \quad (\text{D.2})$$

The amount of acid dopant in sample were calculated from the following equation.

$$\% \text{ element X} = 100 - (\%C + \%H + \%N + \% O_{\text{water}} + \% \text{ Oxidant}) \quad (\text{D.3})$$

$$\% \text{ Appearance doping level} = \frac{\% \text{ Other element} / 14 \text{ g of N} \times 100}{\% \text{ N} \times (\text{atomic mass of X})} \quad (\text{D.4})$$

where X = a residue element; in this work, X is referred to Cl for PANI-HCl, 4-atom O for PANI-MA, and 4-atom O and 1-atom S for PANI-CSA.

Table D1 Calculation of doping level from elemental analysis

Sample	Raw data			% water TGA	% O water	%Oxidant (SO ₄)	%Apparent doping level	% doping level
	%C	%H	%N					
EB	74.251	4.734	14.789	3.69	3.28	2.95	-	-
1HCl	61.542	4.279	11.797	9.02	8.018	2.95	38.17	76.34
10HCl	59.784	4.919	11.404	10.15	9.022	2.95	41.24	82.48
1MA	62.978	4.135	10.512	7.49	6.658	2.95	26.58	53.15
10MA	61.018	3.959	8.748	5.88	5.227	2.95	45.27	90.53
1CSA	62.761	5.825	8.429	5.31	4.72	2.95	26.5	53.01
10CSA	59.834	5.875	6.614	5.88	5.227	2.95	43.01	86.01

The actual doping level is twice of the apparent doping level. So the relative percent doping level can be summarized in Table D1.

APPENDIX E

Determination of the Crystallinity of PANI and Doped PANI

XRD technique was used to investigate the order and the degree of crystallinity of polyanilines. The diffraction patterns of the emeraldine base were typical of an amorphous polymer. On the other hand, all protonic acid doped polyanilines were semi-crystalline polymers. They were identified as follow: the crystalline one corresponds to a relative sharp peak, and the amorphous one is visible as a broad pattern (Lunzy and Banka, 2000). The percentage of crystallinity was determined by integrating area under assumed Guassian curves. Quantitatively, the percentage of crystallinity was calculated from the ratio of the integrated crystalline component intensity to the integrated total intensity.

$$\% \text{ Crystallinity} = \frac{A_{\text{cryst}}}{A_{\text{cryst}} + A_{\text{amorphous}}} \times 100 \quad (\text{E.1})$$

Where A_{cryst} = The area of crystalline peak
 $A_{\text{amorphous}}$ = The area of amorphous peak %Crystallinity

APPENDIX K

Determination of the Correction Factor (K)

The electrical conductivity of sample was measured by a four-point probe meter. Probe head assemblies are available in two different arrangements depending on the probe pins; a linear array and a square array. For the linear array, a constant current (I) was applied to the two outer electrodes and the sample voltage (V) was measured between the two inner electrodes as shown in the figure (appendix figure).

Figure K1 Linear four-point probe array.

The correct factor (K) is used to account the geometrical effects in sheet resistivity measurement of microelectronic structure.

$$K = \frac{w}{l} \quad (\text{K.1})$$

where K is geometrical correction factor
w is width of probe tip spacing (cm)
l is the length between probe (cm)

In this measurement, the constant K value was determined by using a standard sheet with a known resistivity value; we used silicon wafer chips (SiO₂). K was calculated by using Equation K.2.

$$K = \frac{\rho}{R t} = \frac{I}{V} \frac{\rho}{t} \quad (\text{K.2})$$

where	K	=	geometric correction factor
	ρ	=	resistivity of stand materials which were calibrated by using a four point probe at King Mongkut's Institute Technology of Lad Krabang ($\Omega \cdot \text{cm}$)
	t	=	film thickness (cm)
	R	=	film resistance (Ω)
	I	=	current (A)
	V	=	voltage drop (V).

Standard Si wafer were cleaned to remove organic impurities prior to be used according to the standard RCA method (Kern, 1993).

Materials

Acetones (CARLO ERBA, 99.8%), Methanol (CARLO ERBA, 99.9%), Ammonium hydroxide (Merck, 99.9%), Hydrogen peroxide (CARLO ERBA, 30% in water), and dilute (2%) Hydrofuric acid

Experiment

The cleaning procedures contain 3 steps, solvent clean, RCA01 and HF dip. The first step is the solvent clean step, employed to remove oils and organic residues that appeared on Si surface. The Si wafer was placed into the acetone at 55 °C (not excess than 55 °C) for 10 min, removed and placed in methanol for 2-5 min, subsequently rinsed with deionised water and blown dried with nitrogen gas. Second step is the RCA clean, to remove organic residues from silicon wafers. This process oxidized the silicon wafer and left a thin oxide on the surface of the wafer. RCA solution was prepared with 5 parts of water (H_2O), 1 part of 27% ammonium hydroxide (NH_4OH), and 1 part of 30% hydrogen peroxide (H_2O_2). 65 ml of NH_4OH

(27%) was added into 325 ml of DI water in a beaker and then heated to 70 ± 5 °C. The mixture would bubble vigorously after 1-2 minutes, indicated that it is ready to use. Silicon wafer was soaked in the solution for 15 min, consequently overflowed with DI water in order to rinse and remove the solution. The third step is HF dip, which was used to remove native silicon dioxide from wafers. 480 ml of DI water was added to the polypropylene bottle and then added 20 ml HF. Wafer was soaked in this solution for 2 min, removed and checked for hydrophobicity by performing the wetting test. DI water was poured onto the surface wafer, the clean silicon surface would show the bead of water roll off. Clean Si wafer was further blown dried with nitrogen and stored in a clean and dry environment.

APPENDIX L

Determination of Ohmic Regime

The Ohmic regime was defined as the regime which the applied voltage linearly depends on the applied current according to the Ohmic's law.

$$V = IR \quad (L.1)$$

where V_a = applied voltage (mV)
 I = current (mA)
 R = resistance (Ω)

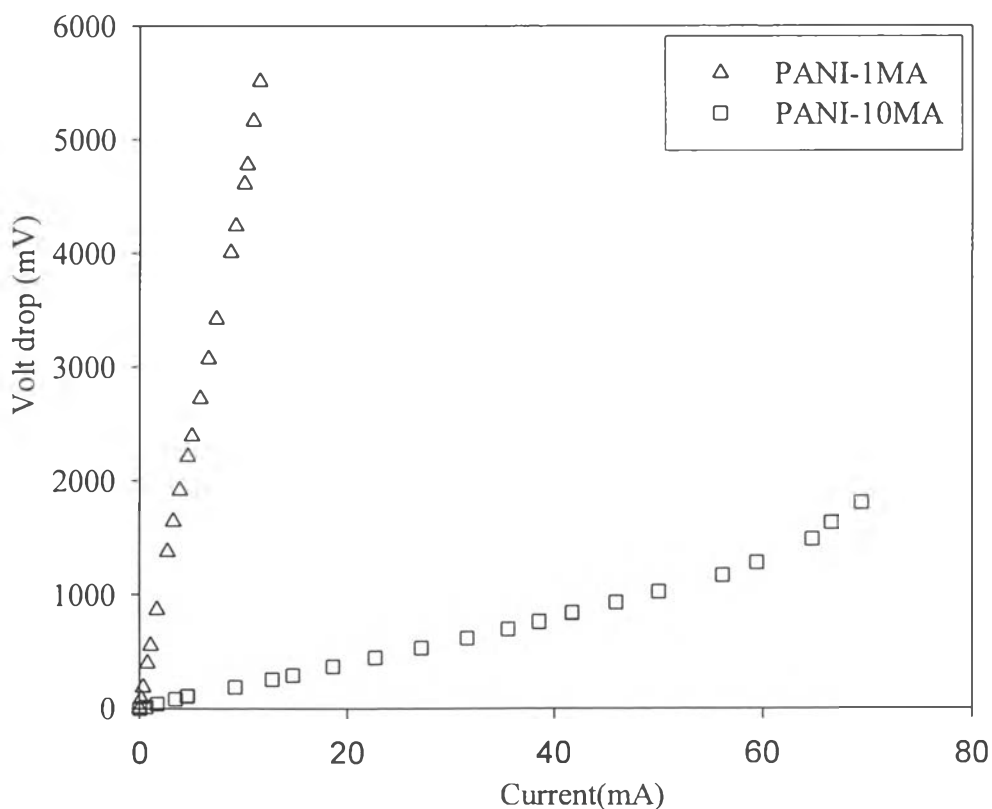

Figure L1 Linear regime of PANI doped maleic acid with $N_A/N_{EB} = 1$ and 10

APPENDIX M

Sensitivity Measurement

Sensitivity measurements of polyaniline and polyaniline-10MA/zeolite pellets were carried by using the four point probe at various CO/N₂ concentrations under the pressure guage of 1 atm, 57-67% relative humidity and 30±2°C. The electrical conductivity response of sample was calculated from the difference between the equilibrium conductivity of sample upon exposed to CO and the steady state of final conductivity of sample in N₂.

$$\Delta\sigma = \sigma_{CO} - \sigma_{Final N_2} \quad (M.1)$$

However, the addition of zeolite into PANI results in the lowering of the initial conductivity of composite sample. So, the sensitivity is defined as the electrical conductivity response divided by the conductivity itself at the N₂.

$$\text{Sensitivity} = \Delta\sigma / \sigma_{N_2, final} \quad (M.1)$$

CURRICULUM VITAE

Name: Ms. Nataporn Densakulprasert

Date of Birth: January 3, 1981

Nationality: Thai

University Education:

1997-2001 Bachelor Degree of Science in Chemistry, Faculty of Science,
King Monkut's University of Technology Thonburi, Bangkok, Thailand.
