KEYWORD: Titanium dioxide, APTMS, rGO, Methylene blue, Photocatalytic degradation

Sirinya Kanjanapanasont : Application of amine-functionalized titanium dioxide wrapped in reduced graphene oxide in photocatalytic degradation of methylene blue. Advisor: Akawat Sirisuk, Ph.D.

This research investigated the effect of reduced graphene oxide (rGO) addition to amine-functionalized titanium dioxide (APTMS-TiO<sub>2</sub>). The loading amount of rGO was varied from 0 to 0.05 %wt. Also, the effect of the amount of 3-aminopropyltrimethoxysilane (APTMS) was studied. To synthesize TiO<sub>2</sub>/rGO catalysts, the amount of APTMS was varied at 2.21 and 22.1 mmol. TiO<sub>2</sub> catalyst was synthesized via a sol-gel method. Next, the surface of TiO<sub>2</sub> was modified with APTMS by refluxing. Then graphene oxide was wrapped around APTMS-TiO<sub>2</sub> and was reduced to rGO using hydrazine and ammonia. In the experiment, the catalyst was dispersed in methylene blue solution before being exposed to either UV or visible light. An increase in the amount of rGO in the catalyst improved photocatalytic activity for degradation of methylene blue. The amount of rGO that produced the highest conversion is 0.04% with the amount of APTMS of 2.21 mmol. Its highest efficiencies were 70.63 % under UV light and 31.06 % under visible light. The conversions of methylene blue degradation over various TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* photocatalysts were in agreement with the results of PL and UV-Vis. Increasing the rGO content resulted in slower recombination rate of charge carrier and better light absorption. Moreover, reducing the APTMS content resulted in narrower bandgap.

## ACKNOWLEDGEMENTS

This thesis would be complete thanks to the following individuals.

Firstly, I would like to express my thesis advisor, Dr.Akawat Sirisuk for his encouragement, support, guidance in both thesis writing and experimentation throughout the course of this research.

Secondly, I would also very grateful to Professor Paisan Kittisuoakorn and Associate professor Kasidit Nootong of the Department of Chemical Engineering at Chulalongkorn University, and Assistant Professor Okorn Mekasuwandumrong of the Department of Chemical Engineering at Silpakorn University as my thesis committee. I am very thankful for the comments and suggestions.

Next, I would also like to thank several friends and scientists at Center of Excellence in Catalysis and Catalytic Reaction Engineering, who always giving advice, teaching the use of analytical instruments.

Finally, I most gratefully my parents for all their support and encouragement throughout the study and period of this thesis.

## CHAPTER 1

### INTRODUCTION

Currently, water pollution is one of the major environmental problems. One of the reasons is the rapid expansion of textile and printing industries [1]. Therefore, it is necessary to treat polluted water before releasing it into the environment. But a large portion of wastewater contaminated with dyes is difficult to treat because of the complex composition and high concentration of organic substances.

In general, there are 3 methods for wastewater treatment. First, the physical treatment method separates non-soluble substances from wastewater such as filtration, screening, sedimentation, and skimming. However, these processes have high operating costs [2]. Second, the biological treatment employs microorganisms to decompose and convert organic substances matter into carbon dioxide and ammonia. Microorganisms that used to decompose organic substances such as biofilms, sludge, and granules [3] needs an optimum condition for microbial work and takes a long time to decompose. This method is not suitable for dye degradation [1, 2]. Last, the chemical treatment adds various chemicals to eliminate contaminants, but this process has many effects on the environment such as  $H_2O_2$ , chlorine, sulfate, and heavy metal [2]. However, titanium dioxide ( $TiO_2$ ) photocatalysis is environmentally friendly. Therefore, this research focuses on green technology, while trying to reduce the cost of wastewater treatment. As a result, the treatment chosen by this research is photocatalytic process.

In many years, titanium dioxide is a semiconductor used in a photocatalytic process under both UV and visible irradiations. When the electron in a valence band (VB) of  $TiO_2$  receives energy from the photon, it becomes excited from the valence band up to the conduction band (CB). Then the photogenerated electron reacts with oxygen molecule ( $O_2$ ) to produce superoxide radical anions ( $\bullet O_2^-$ ) and the product from positive hole ( $h^+$ ) reaction with water molecule is hydroxyl radicals ( $\bullet OH$ ) [4]. Both superoxide radical anions and hydroxyl radicals can promote the oxidation and dye degradation to

H<sub>2</sub>O, CO<sub>2</sub>, and other small molecules. The result of this reaction is that the dye in the wastewater is eliminated.

Generally, titanium dioxide (TiO<sub>2</sub>) comprises 3 forms of polymorph in nature, namely, anatase, rutile, and brookite [5]. TiO<sub>2</sub> is also widely used due to its mechanical strength, long-term stability, strong oxidation ability, high activity, environmental-friendly, non-toxicity, and non-expensive [4, 6, 7]. However, TiO<sub>2</sub> possesses a wide bandgap [4]. Therefore, many researchers studied the improvement of TiO<sub>2</sub> photocatalyst for greater efficiency.

In a photocatalytic process, the photogenerated electron-hole pairs in TiO<sub>2</sub> semiconductor can recombine quickly [8], thereby lowering its performance. Therefore, we incorporated reduced graphene oxide (rGO) into the system by wrapping TiO<sub>2</sub> surface with rGO to increase its photocatalytic activity [9], improve the surface-adsorbed chemical molecules through  $\pi$ - $\pi$  interactions [10, 11], and extend the light absorption range into visible region [12].

To synthesize TiO<sub>2</sub>/rGO catalyst, TiO<sub>2</sub> surface must be modified with 3-aminopropyl-trimethoxysilane (APTMS) first. The amine group anchored on the TiO<sub>2</sub> surface has a positive charge and attracts rGO with a negative charge while being wrapped on the TiO<sub>2</sub> surface. When TiO<sub>2</sub> was wrapped with rGO, recombination electrons and holes become slower [9, 12].

In this research, we chose methylene blue as a model organic dye contaminant. The photocatalytic degradation of methylene blue under UV and visible irradiations in aqueous phase based on TiO<sub>2</sub>/rGO catalyst was studied (as seen in Figure 1).

Figure 1 Schematic diagram of the proposed toward photocatalytic of methylene blue over TiO<sub>2</sub>/rGO photocatalyst under UV or visible irradiation.

## 1.2 Objectives

1. To improve photocatalytic activity of TiO<sub>2</sub> photocatalyst by wrapping with rGO.
2. To investigate effects of the amount of rGO and amine group on the photocatalytic activities of the TiO<sub>2</sub>/rGO in methylene blue degradation.

## 1.3 Research scopes

### 1.3.1 Synthesis of titanium dioxide/reduce graphene oxide (TiO<sub>2</sub>/rGO)

1. TiO<sub>2</sub> was synthesized via a sol-gel method.
2. GO was synthesized from graphite powder using modified Hummers method.
3. GO was reduced to rGO with hydrazine and ammonia solution.
4. The concentration of APTMS was varied at 2.21 and 22.1 mmol.
5. TiO<sub>2</sub>/rGO was prepared by heating and refluxing at 95-100°C for 24 hours.
6. The amount of rGO was varied from 0 to 0.05 g.

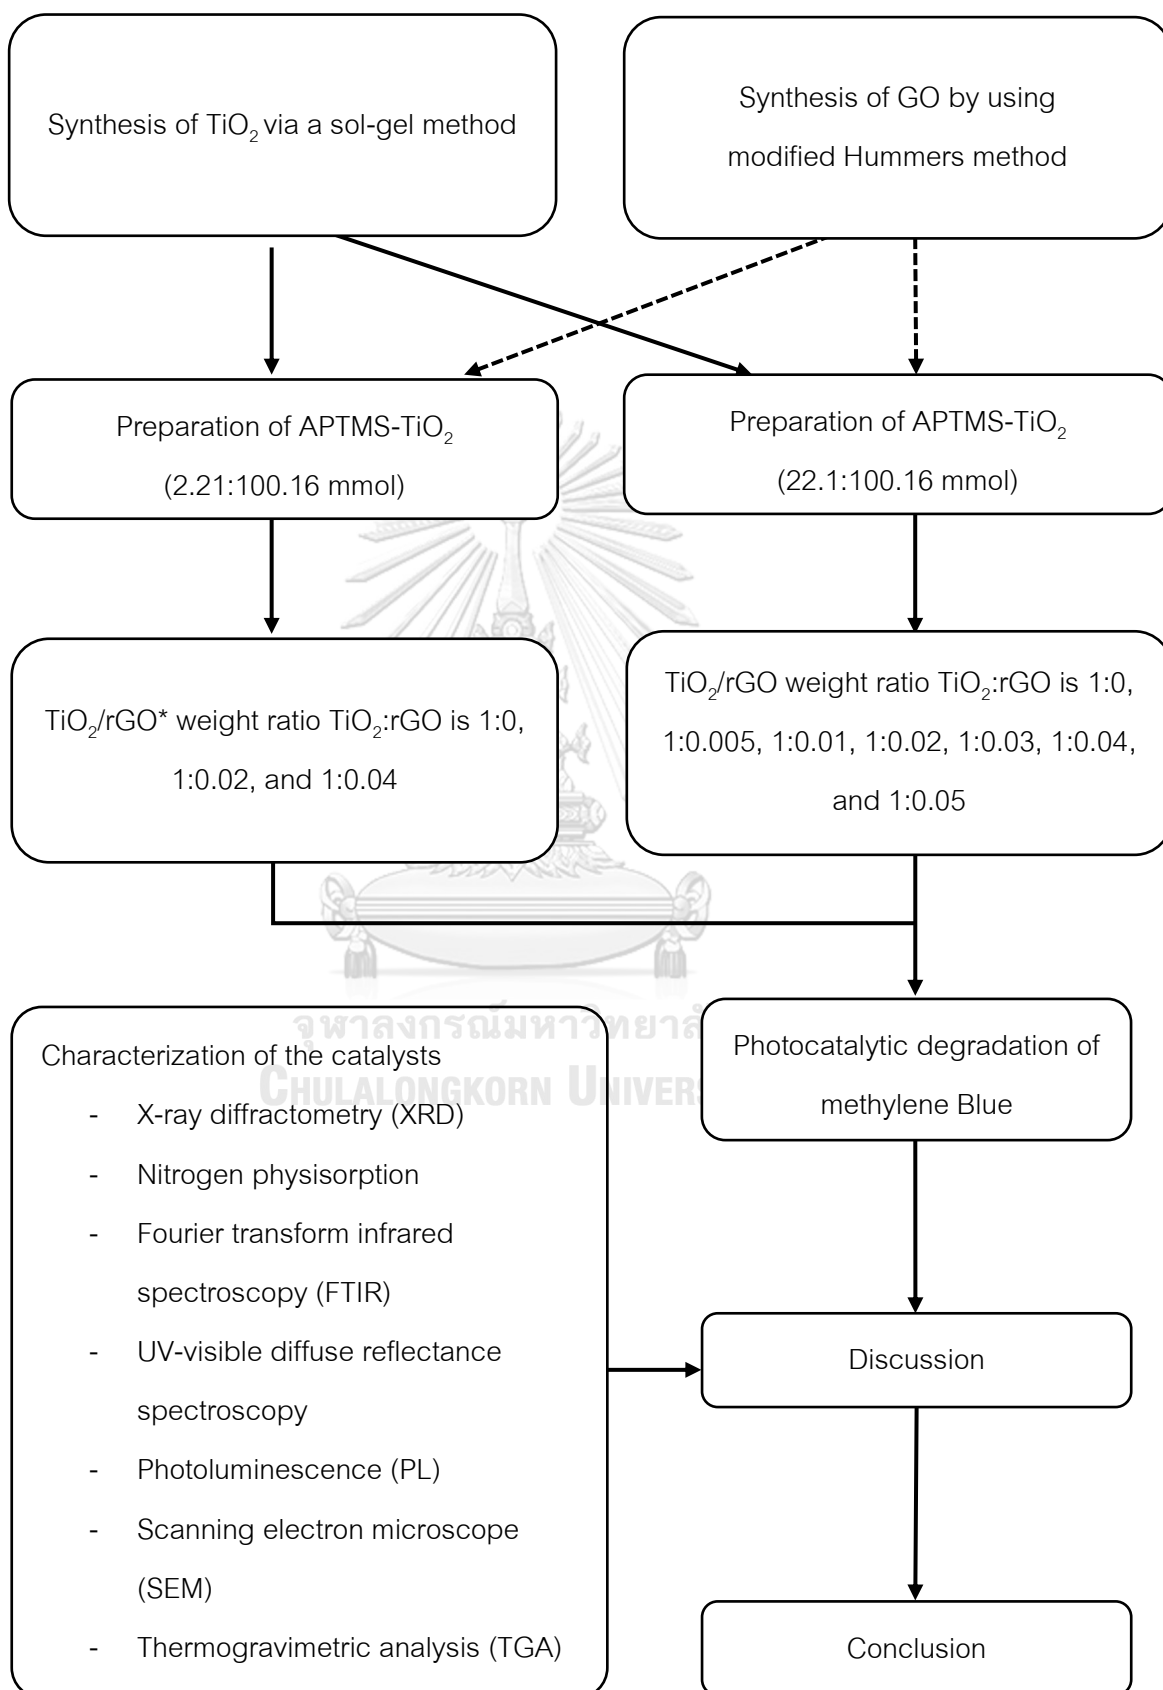

### 1.3.2 Characterization of the TiO<sub>2</sub>/rGO catalysts

1. X-ray diffractometry (XRD)
2. Nitrogen physisorption
3. Fourier transform infrared spectroscopy (FTIR)
4. UV-visible diffuse reflectance spectroscopy
5. Photoluminescence spectroscopy (PL)
6. Scanning electron microscope (SEM)
7. Thermogravimetric analysis (TGA)

### 1.3.3 The photocatalytic activity testing

1. The photocatalytic activities for methylene blue degradation in aqueous phase over TiO<sub>2</sub>/rGO catalysts under either UV or visible irradiation were investigated.
2. The concentration of methylene blue was measured by UV-visible spectrophotometer at the wavelength of 665 nm.

## 1.4 Research methodology

## CHAPTER 2

### THEORY

#### 2.1 Titanium dioxide

Titanium dioxide ( $\text{TiO}_2$ ) or titania is commonly used in many industries including paints, cosmetics, electronics, filter coating, biomedicine, dye-sensitized solar cells and catalysts [13]. The properties of  $\text{TiO}_2$  as seen in Table 1. In 1972, Fujishima and Honda introduced titanium dioxide as a semiconductor to photocatalytic decomposition of water splitting under UV irradiation [14].

**Table 1** The chemical and physical properties of titanium dioxide ( $\text{TiO}_2$ ) [13]

Molecular Formals	$\text{TiO}_2$
Molecular weight	79.866 g/mol
Melting point	1844 °C
Boiling point	2973 °C
Refractive index	Anatase Rutile Brookite
Appearance	White solid
Solubility	Insoluble in water
Odor	Odorless

In general, titanium dioxide has 3 crystalline phases, namely, rutile, anatase, and brookite (as seen in Table 2 and Figure 2). Rutile phase is the stable phase because anatase and brookite phases when heated can be transformed to rutile phase [6]. The stability of crystalline phases of titanium dioxide is in the order of rutile > brookite > anatase [5]. However, anatase phase of  $\text{TiO}_2$  is more active than rutile and brookite  $\text{TiO}_2$  phases in terms of a photocatalytic activity. Still anatase has drawback due to a larger bandgap [4].

Table 2 Types of TiO<sub>2</sub> polymorphs and physical properties [13].

Crystal structures	Crystal system	Density (g/cm <sup>3</sup> )	Optical bandgap (eV)	Refractive index
Rutile	Tetragonal	4.13-4.26	3.0	2.72
Anatase	Tetragonal	3.79–3.84	3.19	2.52
Brookite	Orthorhombic	3.99-4.11	3.11	2.63

Figure 2 TiO<sub>2</sub> crystal structures of (a) rutile, (b) anatase, and (c) brookite [13]

In photocatalysis, when TiO<sub>2</sub> photocatalyst is activated by UV or visible irradiation with energy larger than bandgap energy, photogenerated electron (e<sup>-</sup>) in the VB excited to CB and left behind a h<sup>+</sup> in the VB. A hole reacts with water to produce •OH, which degrades dye into CO<sub>2</sub>, H<sub>2</sub>O, and other products (shown in Equations (1) to (6) below) [6].

## 2.2 Sol-gel method

The sol-gel is a commonly method used for the synthesis of  $\text{TiO}_2$  from precursors which solid particles (precursors) convert to colloidal solution (sol) and integrated network (gel) [15]. This method can prepare solids at low temperatures. The chemical reaction of the sol-gel method is based on hydrolysis and condensation reactions [16] as seen in Equations (7) to (9).

Where R is alkyl group such as ethyl, i-propyl, and n-butyl

## 2.3 Graphene oxide

### 2.3.1 Structure and properties of graphene oxide

Graphene or monolayer sheet of graphite arranged in a honeycomb structure, where each carbon atom is held together by a covalent bond [17]. It is produced by the oxidation of graphite using oxidizing agent in acidic solution.

Graphene oxide (GO) has various functional groups on sheet such as hydroxyl, epoxide, and carbonyl [18]. It possesses large high surface area, attractive mechanical, electronic, thermal and optical properties.

### 2.3.2 Synthesis of graphene oxide

The preparation of GO from graphite as seen in Figure 3. There are 3 principal methods for synthesis of graphene oxide developed by Brodie, Staudenmeier, and Hummers, respectively.

Brodie method [19] is the first method for the synthesis of graphene oxide in 1859. Fuming nitric acid was mixed with graphite powder and potassium chlorate, an oxidizing agent, was later added. The resulting product was a mixture of graphene and graphite oxide. The elemental analysis found that the product contained 60% C, 2% H and 38% O. But this reaction is still dangerous.

Staudenmeier method [20] was improved further from Brodie's method. An acidic mixture was prepared by mixing adding sulfuric acid and potassium chlorate. Both Brodie and Staudenmaier methods have a byproduct as chloride toxic gas, which can decompose rapidly in the air, causing the explosion. But graphite is more oxidized.

For Hummers method [21], potassium permanganate and sodium nitrate are mixed with graphite in sulfuric acid. After that, hydrogen peroxide was poured into the suspension to eliminate manganese ions. In general, graphene oxide that is synthesized from this method have flakes about 1 nm and a lateral size of 1  $\mu\text{m}$ .

Figure 3 Schematic representation of the preparation of GO graphite, (b.) graphite oxide, and (c.) graphene oxide [9]

## 2.4 Reduce graphene oxide

Reduce graphene oxide (rGO) is a product of a reduction of graphene oxide by eliminating the oxygen-containing groups with the recovery of a conjugated structure by chemical reaction (see Figure 4) [12]. Several reducing agents can be used such as hydrazine [22], ammonia [23, 24], ascorbic acid [25], and sodium borohydride [26]. The rGO can be applied in battery [27], dye-sensitized solar cell [28], biosensor [29], and catalyst [9, 30-33].

Figure 4 Chemical structures of graphite, graphene oxide and reduced graphene oxide and graphene [34].

## 2.5 3-Aminopropyl-trimethoxysilane

The compounds, 3-aminopropyl-trimethoxysilane (APTMS) has a molecular weight of 179.29 g/mol (see Figure 5). In general, APTMS is often used to modify the surface of the catalyst to enhance its performance, such as  $\text{TiO}_2$  [10, 35],  $\text{Fe}_3\text{O}_4$  [36],  $\text{ZnO}$  [37], and MCM-41 [38].

Figure 5 Structure of 3-aminopropyl-trimethoxysilane

## 2.6 Methylene blue

### 2.6.1 Structure and properties of methylene blue

Methylene blue is a dye commonly used in the textile industry, which is classified as a heterocyclic aromatic compound with chemical name 3,7-bisdimethylamino phenazathionium chloride trihydrate ( $\text{C}_{16}\text{H}_{18}\text{ClN}_3\text{S}\cdot 3\text{H}_2\text{O}$ ) (see Figure 6) [39]. It has a dark blue-green color. Sometimes called this type of dye is cationic thiazine dye. It is widely used in a number of areas such as medicine, biology, and chemical indicator. In human, methylene blue is toxic if received in large quantities and the body will be affected such as increased heart rate, vomiting, chest pain, shock, and bluish discoloration of skin [40].

Figure 6 Structure of methylene blue

## 2.7 Photocatalytic degradation pathway of methylene blue

The pathway for the photocatalytic degradation of methylene blue dyes by  $\text{TiO}_2$  is shown in Figure 7. The decomposition products are detected by GC/MS and LC/MS [41].

(a) detected by GC/MS ( extraction of ions)  
 (b) detected by LC / MS

Figure 7 Photocatalytic degradation pathway of methylene blue [6]

## CHAPTER 3

### LITERATURE REVIEWS

#### 3.1 Effects of amine group added to titanium dioxide on properties

Klaysri et al. [35] studied the effect of 3-aminopropyltriethoxysilane (APTES) used to modified the surface of  $\text{TiO}_2$  on conversions of methylene blue decolorization under visible irradiation. The APTES- $\text{TiO}_2$  catalysts investigated contained APTES at 0.1, 1.0, and 10 mM. The 0.1 mM APTES- $\text{TiO}_2$  exhibited the highest conversion because the monolayer of aminosilane coverage on  $\text{TiO}_2$  surface narrowed the bandgap, resulting in a decrease in rate of electron-hole recombination.

Iijima et al. [42] studied the effect of ratio of mixed silane alkoxides on reactivity with  $\text{TiO}_2$  nanoparticle surface and stability in organic solvents. Hydrophilic  $\text{TiO}_2$  nanoparticles were synthesized using a mixture of decyltrimethoxysilane/3-aminopropyltrimethoxysilane (DTMS/APTMS) and phenyltrimethoxysilane/3-aminopropyltrimethoxysilane (PTMS/APTMS) by varying the amount of DTMS, APTMS, and PTMS. As a result, during the modification process, the pH value increased when APTMS was added to  $\text{TiO}_2$  nanoparticle suspension. Highly hydrophobic silane ratio of  $\text{TiO}_2$  can re-dispersible into low-polar solvents such as hexane, toluene, and THF. By the addition of hydrophilic silanes to  $\text{TiO}_2$  surface, hydrophilic  $\text{TiO}_2$  nanoparticles were dispersible in highly polar solvents such as NMP, DMAc, and DMSO.

Fadillah et al. [43] investigated the effect of surface modification  $\text{TiO}_2$  nanorods with APTMS. This research successfully grafted amine group onto  $\text{TiO}_2$  surface by Ti-O-Si chemical bonds. The N3 complex-APTMS enhanced the visible light absorption of  $\text{TiO}_2$ .  $\text{TiO}_2$ ,  $\text{TiO}_2$ -APTMS 5%,  $\text{TiO}_2$ -APTMS 10%, and  $\text{TiO}_2$ -APTMS 15% were studied and the best result was obtained from 10 % (v/v) APTMS in terms of efficiency of dye-sensitized solar cell.

Kominami et al. [44] modified the surface of  $\text{TiO}_2$  with APTMS for nitrogen oxides ( $\text{NO}_x$ ) removal. As a result, modification with APTMS inhibited  $\text{TiO}_2$  crystal growth and transformation of anatase to rutile  $\text{TiO}_2$  during the calcination process, resulting in improved thermal stability of the support. The  $\text{V}_2\text{O}_5/\text{TiO}_2$  catalyst had a strong interaction between the protonated amino group in the modified  $\text{TiO}_2$ . The  $\text{V}_2\text{O}_5/\text{TiO}_2$  catalyst, of which the surface was modified with APTMS had a large surface area and higher activity than the  $\text{V}_2\text{O}_5/\text{TiO}_2$  prepared from an unmodified catalyst (as seen in Figure 8).

Figure 8 TEM photographs of samples after calcination of (a) unmodified  $\text{TiO}_2$ , (b) APTMS- $\text{TiO}_2$  at  $550\text{ }^\circ\text{C}$  [44]

Zhao et al. [45] investigated the effect of surface modification with 3-aminopropyltrimethoxysilane (APTMS) and 3-isocyanatopropyltrimethoxysilane (IPTMS) on surface properties of  $\text{TiO}_2$  nanoparticles. As the ratio of organosilane was increased from 0 %wt to 200 %wt, the rate constant for APTMS- $\text{TiO}_2$  photocatalytic activity was slightly lower. On the other hand, the rate constant for IPTMS- $\text{TiO}_2$  quickly dropped because IPTMS is more effective in grafting than APTMS.

Pasqui et al. [46] studied the preparation of self-cleaning textile fabrics by  $\text{TiO}_2$  nanoparticles grafted polyester fibers. In sample preparation,  $\text{TiO}_2$  surface was modified first with the APTMS so that the Si-O-Ti bond has interacted with polyester fibers.

Therefore, APTMS-TiO<sub>2</sub> was grafted with polyester fibers. From the results, the sample was effective in removing methylene blue stains well within 3 hours under UV irradiation.

### 3.2 Effects of GO and rGO in a photocatalytic process

Sun et al. [47] studied of the application of rGO in various G/TiO<sub>2</sub>, G/ZnO and G/Ta<sub>2</sub>O<sub>5</sub> composite photocatalyst and investigated the photocatalytic activities of the composites for the photodegradation of methylene blue under UV-vis and visible light. For the results of the degradation of methylene blue in visible light, graphene enhanced the activity in the visible region in G/TiO<sub>2</sub> catalyst greater than other composites. For the degradation of methylene blue under UV-vis light with TiO<sub>2</sub> and G-TiO<sub>2</sub> catalysts decomposed 100% of methylene blue after 110 minutes. The ZnO and G/ZnO catalysts degraded methylene blue 100% under UV-vis light after 30 and 60 minutes respectively, which were more efficient than TiO<sub>2</sub> and G/TiO<sub>2</sub> catalysts. On the other hand, they had low efficiencies under visible light. Next, the Ta<sub>2</sub>O<sub>5</sub> and G/Ta<sub>2</sub>O<sub>5</sub> catalysts degraded 50.2 and 72.1% of methylene blue after 120 minutes under UV-vis light but the G-Ta<sub>2</sub>O<sub>5</sub> catalyst was not very active in degrading methylene blue under visible light because it has a wide bandgap of 3.67 eV (as seen in Figure 9).

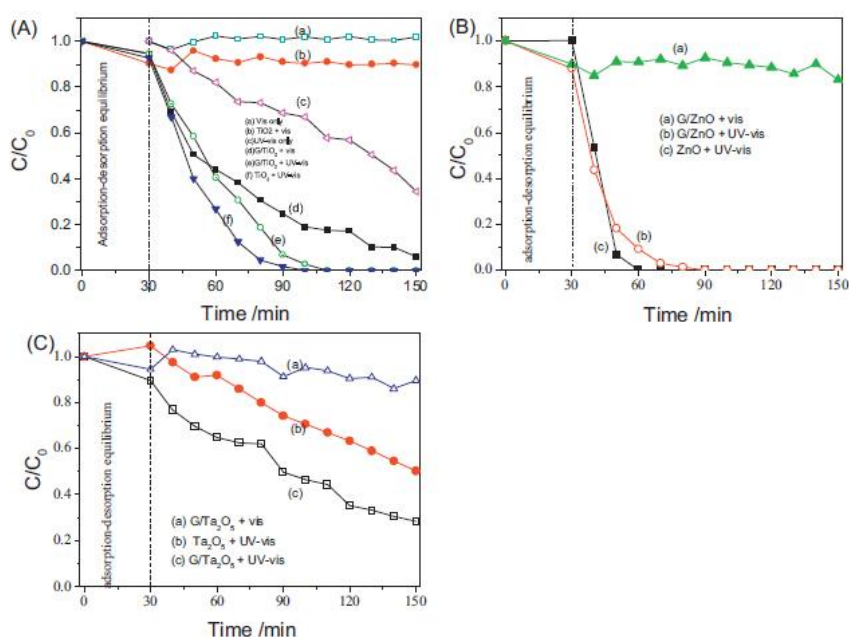

Figure 9 Photocatalytic oxidation of methylene blue at various conditions.

(A) TiO<sub>2</sub> and G/TiO<sub>2</sub>, (B) ZnO and G/ZnO, and (C) Ta<sub>2</sub>O<sub>5</sub> and G/Ta<sub>2</sub>O<sub>5</sub> [47]

Ni et al. [10] studied the effect of rGO wrapping on the surface of highly-reactive anatase by modifying the surface of  $\text{TiO}_2$  via a hydrothermal method. The structure of rGO wrapped  $\text{TiO}_2$  is called a core-shell structure. This structure lessened the bandgap more than the rGO-supported  $\text{TiO}_2$ . The performance was investigated by photodegradation of methylene blue under UV and visible irradiation.

Zou et al. [48] studied the effects of congo red degradation by CdS-rGO nanocomposites under simulated sunlight irradiation. The photocatalytic activity and stability of CdS-rGO nanocomposites was improved, compared with CdS nanoparticles and CdS/GO mixture because rGO sheets enhanced light conversion efficiency, decrease the recombination of electron-hole pairs, and promote the charge separation.

Amaranatha et al. [49] studied the enhanced photocatalytic activity of ZnS- $\text{Ag}_2\text{S}$  wrapped with rGO in degrading rhodamine B solution under simulated sunlight irradiation. The ZnS- $\text{Ag}_2\text{S}$ -rGO nanocomposite was synthesized by hydrothermal method without any surfactant. The photocatalytic ability of ZnS - $\text{Ag}_2\text{S}$ -rGO nanocomposite was the highest among ZnS, ZnS-rGO,  $\text{Ag}_2\text{S}$ ,  $\text{Ag}_2\text{S}$ -rGO, and ZnS- $\text{Ag}_2\text{S}$ . As a result, rGO sheet which has good conductivity, facilitated the charge transfer between ZnS to  $\text{Ag}_2\text{S}$ , thereby increasing the photocatalytic ability of ZnS- $\text{Ag}_2\text{S}$ -rGO nanocomposite.

Li et al. [30] investigated the effect of gold and various amounts of rGO added to  $\text{TiO}_2$  catalyst.  $\text{TiO}_2$ , Au/ $\text{TiO}_2$ , and  $\text{TiO}_2/\text{Au@rGO}$  hybrids were synthesized and used the decomposition of methyl orange under UV and simulated solar light. GO was reduced to rGO via hydrazine and ammonia. The  $\text{TiO}_2/\text{Au@rGO}$  hybrids promoted multi-channel electron transfer paths, resulting in the best performance compared to  $\text{TiO}_2$  and Au/ $\text{TiO}_2$ . And the amount of rGO added in the range of 0.25-0.75 %w/w provides the highest efficiency. On the other hand, an increase in rGO, decreased the degradation of methyl orange because the excessive rGO was obscuring the light.

## CHAPTER 4

### EXPERIMENTAL

This chapter describes the detail of chemicals and methods used in catalytic preparations, photocatalytic test, and characterization of catalyst.

#### 4.1 Materials and chemicals

**Table 3** List of chemicals in this research

Chemicals	Formula	Brand
Graphite	C	Fluka
Sodium nitrate	NaNO <sub>3</sub>	Fluka
Sulfuric acid	H <sub>2</sub> SO <sub>4</sub>	Merck
Potassium permanganate	KMnO <sub>4</sub>	Suksapanpanit
Hydrogen peroxide	H <sub>2</sub> O <sub>2</sub>	Aldrich
Hydrochloric acid	HCl	Qrec
Ethanol	CH <sub>3</sub> CH <sub>2</sub> OH	Merck
Methanol	CH <sub>3</sub> OH	RCI Labscan
Titanium(IV)isopropoxide	TiOCH(CH <sub>3</sub> ) <sub>2</sub>	Aldrich
Nitric acid	HNO <sub>3</sub>	RCI Labscan
(3-Aminopropyl)trimethoxysilane	H <sub>2</sub> N(CH <sub>2</sub> ) <sub>3</sub> Si(OCH <sub>3</sub> ) <sub>3</sub>	Aldrich
Hydrazine solution	N <sub>2</sub> H <sub>4</sub>	Aldrich
Ammonia solution	NH <sub>3</sub>	Qrec
Toluene	C <sub>6</sub> H <sub>5</sub> CH <sub>3</sub>	Merck
Diethyl ether	(C <sub>2</sub> H <sub>5</sub> ) <sub>2</sub> O	Merck
Methylene blue	C <sub>16</sub> H <sub>18</sub> N <sub>3</sub> ClS·2H <sub>2</sub> O	UNILAB

#### 4.2 Preparation of TiO<sub>2</sub>/rGO catalyst

##### 4.2.1 Synthesis of GO

GO was synthesized using a modified Hummers method. In a typical synthesis procedure, 50 mL of concentrated sulfuric acid was cooled to 4 °C in an ice bath. Then

2.0 g of graphite powder and 1.0 g of  $\text{NaNO}_3$  were added to the concentrated  $\text{H}_2\text{SO}_4$ . Next,  $\text{KMnO}_4$  was put gradually into a mixture while being stirred for 2 hours. Then the mixture was stirred continuously at room temperature for 30 minutes. After that, 100 mL of deionized (DI) water was poured carefully into a mixture. The mixture was slowly heated to 90 °C under constant stirring for 3 hours. Later, 50 mL of 5%  $\text{H}_2\text{O}_2$  solution was added to eliminate residual  $\text{MnO}_4^-$  and the mixture was stirred for 1 hour. Finally, GO aqueous suspension was centrifuged, washed by 5% HCl, DI water and ethanol several times until the pH of rinse water became neutral. The product was dried at 60 °C in oven overnight.

#### 4.2.2 Synthesis of $\text{TiO}_2$ nanoparticles [50]

The first step in the synthesis of  $\text{TiO}_2$  via a sol-gel method was pouring the 1000 mL of DI water into the flask. After that, 83.33 mL of titanium(IV)isopropoxide was added to the solution. Then 7.25 mL of 65%  $\text{HNO}_3$  was added and the mixture became milky suspension. The suspension was stirred continuously for 3 days until the mixture became clear. Next, the sol was dialyzed inside cellulose membranes with a molecular weight cutoff of 3500 in DI water until the pH value reached 3.8. Finally, the sol was dried, crushed, and calcined at 400 °C for 2 hours with a heating rate 10 °C /minutes.

#### 4.2.3 Surface modification of $\text{TiO}_2$ with APTMS [44]

In this process, 8.0 g of  $\text{TiO}_2$  was dispersed in 80 mL of anhydrous toluene with the assistance from ultrasonication for 30 minutes. The concentrations of APTMS, we were investigated in were 2.21 and 22.1 mmol. The reaction mixtures were then refluxed at 110 °C and stirred for 8 hours. After that, the mixtures were centrifuged and washed with toluene, diethylether, and methanol to remove other residual chemicals. Ultimately, modified particles were dried in oven at 60 °C in oven overnight. The products were represented as APTMS- $\text{TiO}_2$  (2.21 mmol) and APTMS- $\text{TiO}_2$  (22.1 mmol), respectively.

#### 4.2.4 Fabrication of TiO<sub>2</sub>/rGO catalyst

In the synthesis of TiO<sub>2</sub>/rGO catalysts. The surface of TiO<sub>2</sub> was wrapped with rGO according to the following steps. Initially, different amount of GO (0, 0.005, 0.01, 0.02, 0.03, 0.04 and 0.05 g) was dispersed into 500 mL of deionized water under sonication for 30 minutes. This process dispersed the layers of graphite oxide to produce graphene oxide sheets [51]. After that, 1.0 g of APTMS-TiO<sub>2</sub> (22.1 mmol) powder was dispersed in GO suspension and kept sonicated for 30 minutes. In the reduction process of GO to rGO, 35% hydrazine in water solution and 28% ammonia in water solution were added in GO suspension using the volumetric ratio of hydrazine:ammonia of 0.5:3.5 [24, 52]. After heating and refluxing at 95-100 °C for 24 hours, the mixture was separated by centrifugation and was washed with DI water and absolute alcohol several times, and finally dried at 60 °C for 24 hours. The final products were referred to as TiO<sub>2</sub>/rGO (1:0), TiO<sub>2</sub>/rGO (1:0.005), TiO<sub>2</sub>/rGO (1:0.01), TiO<sub>2</sub>/rGO (1:0.02), TiO<sub>2</sub>/rGO (1:0.03), TiO<sub>2</sub>/rGO (1:0.04), and TiO<sub>2</sub>/rGO (1:0.05). The synthesis of TiO<sub>2</sub>/rGO\* catalysts with APTMS-TiO<sub>2</sub>(2.21 mmol) followed a similar procedure but the amounts of rGO were varied from 0, 2, and 4 g and were referred to as TiO<sub>2</sub>/rGO (1:0)\*, TiO<sub>2</sub>/rGO (1:0.02)\* and TiO<sub>2</sub>/rGO (1:0.04)\*, respectively.

#### 4.3 Photocatalytic experiments

The photocatalytic activity of the TiO<sub>2</sub>/rGO catalyst was investigated by measuring the conversion of methylene blue for the photodegradation under UV and visible light irradiations at room temperature. First, 400 mL of methylene blue (10 mg/L) solution was charged in the double jacketed glass reactor. Then 0.4 g of catalyst was dispersed by stirring continuously. The system was kept in the dark for 1 hour to establish the adsorption-desorption equilibrium of methylene blue. Afterward, the suspension was irradiated by either UV irradiation using 75W UV-C lamp or visible light irradiation using 18W TL-D standard colors lamp (as seen in Figure 10). During the reaction, 5 mL of methylene blue solution was collected every 15 minutes for 3 hours. The concentration of methylene blue was measured using a UV-Vis spectrophotometer with a maximum

absorption wavelength of 665 nm. The percentage of degradation was calculated with the following equation given below:

$$\% \text{Degradation} = \frac{C_0 - C_t}{C_0} \times 100 \quad (7)$$

Where  $C_0$  is the initial concentration of methylene blue and  $C_t$  is the concentration of methylene blue after treatment with  $\text{TiO}_2/\text{rGO}$  photocatalyst.

CHULALONGKORN UNIVERSITY  
Figure 10 Photocatalysis reaction experimental setup

#### 4.4 Catalyst characterization

##### 4.4.1 X-ray diffractometry (XRD)

The X-ray diffraction (XRD) patterns were obtained using an X-ray diffractometer (Bruker D8 Advance) with a  $\text{CuK}\alpha$  irradiation source and at the angle range between  $20^\circ$  to  $80^\circ$  with a scan speed of 0.5 sec/step and a receiving slit with 0.6 mm width.

The crystallite size was calculated using the Scherrer equation [53] given below:

$$D = \frac{k\lambda}{\beta \cos\theta} \quad (10)$$

Where D is the size of the particle,  $\lambda$  is the X-ray wavelength (For CuK $\alpha$  radiation using 1.54439 Å),  $\beta$  is the pure diffraction broadening, and  $\theta$  is the diffraction angle of the peak, and k is the crystallite shape factor.

#### 4.4.2 Nitrogen physisorption

The surface area and pore volume of catalysts were measured in a Micromeritics ASAP 2020 instrument. This analysis using 30% nitrogen gas in helium gas as a carrier gas and used liquid nitrogen in adsorption process. Generally, 0.05 g of the catalyst was placed inside the glass cell. Before analyzing, all samples were heated at 110 °C for 24 hours.

#### 4.4.3 Fourier transform infrared spectroscopy (FTIR)

The FTIR spectroscopy, which is a technique used to identify functional groups of catalysts, were obtained under an ATR mode in the wavelength 4000-400 cm<sup>-1</sup> region. The FTIR spectra of catalysts were obtained using a Thermo Scientific Nicolet 6700 FT-IR spectrometer.

#### 4.4.4 UV-visible spectroscopy

The UV-visible spectroscopy measures the intensity of light absorbed after it passes through sample in the wavelength range from 200-800 nm. This technique measured the concentration of methylene blue. The concentration of methylene blue collected after the photocatalytic reaction at different time periods were measured by Perkin Elmer Lambda 650 spectrophotometer at the wavelength of 665 nm.

The UV-vis spectrum was also used to calculate the band gaps of semiconductor material (see Appendix D).

#### 4.4.5 Photoluminescence spectroscopy (PL)

Photoluminescence spectroscopy investigated the charge separation of photogenerated electron and hole as well as charge-carrier lifetimes of semiconductors. The sample was excited using a Xenon lamp with an excitation wavelength of 325 nm at room temperature by Horiba Fluoromax-4P spectrofluorometer.

#### 4.4.6 Scanning electron microscope (SEM)

SEM was used to study the morphology of the materials using JEOL model JSM-5800LV. Before analysis, the sample was heated at 110 °C overnight. After that, SEM samples were loaded on carbon tape and coated by platinum.

#### 4.4.7 Thermogravimetric analysis (TGA)

TGA is a technique used to determine the thermal stability of materials. The sample was analyzed by a TA Instrument SDT-Q600 DSC-TGA in an air atmosphere. The temperature of the analysis was run from 30-1000 °C.

## CHAPTER 5.1

### RESULTS AND DISCUSSION OF SYNTHESIS OF GRAPHENE OXIDE AND REDUCED GRAPHENE OXIDE

The results and discussion in chapter 5.1 are classified into two major parts. In the first part, several characterization techniques for the GO and rGO including TGA, UV-vis, FTIR, and SEM-EDX are described. The second part describes the adsorption of methylene blue on rGO in the dark. The decrease in concentration of methylene was detected by UV-Vis spectrophotometer.

#### 5.1.1 Characterization of the graphene

##### 5.1.1.1 TGA analysis

TGA analysis detected the weight loss of the GO and rGO. The sample was heated under air atmosphere. The weight loss was observed around 100 °C which was attributed to evaporation of adsorbed water. A significant weight loss occurred at 200 °C from decomposition of oxygen-containing functional group of GO. A severe weight loss of rGO in a temperature range of 500-600 °C was a result of the destruction of carbon skeleton (carbonyl and double bond) in graphene [54]. Based on the result, rGO exhibited higher thermal stability than GO because rGO contained fewer oxygen-containing functional groups than GO did.

Figure 11 TGA of (s) GO and (r) rGO

#### 5.1.1.2 Light absorption properties

To compare the light absorption performance of GO and rGO, the samples were exposed to light in the wavelength range of 200–800 nm (see Figure 12). Because the structure of GO had aromatic C=C bonds and C bonds that reacted with oxygen groups, the absorbance of GO was lower [55]. When GO reduced to rGO, there was a decrease in the amount of oxygen group in the structure. The rGO absorption value became greater. Therefore, rGO was more suitable than GO to be incorporated into the photocatalyst.

Figure 12 UV-vis spectra of (s) GO and (r) rGO

#### 5.1.1.3 FTIR analysis

The FTIR spectra identified the functional groups in GO and rGO as seen in Figure 13. In the synthesis of GO from graphite by modified Hummer's method, In Figure 13(s) a broad band was observed at  $3234.1\text{ cm}^{-1}$ , which corresponded to OH stretching vibration [56]. The peak at  $1717.1\text{ cm}^{-1}$  was assigned to the stretching vibration of C=O group [57]. The band observed at  $1371.6\text{ cm}^{-1}$  and  $1061.2\text{ cm}^{-1}$  corresponded to C-OH and C-O respectively [58]. In addition, the strong peak at the  $1623.1\text{ cm}^{-1}$  corresponded to C=C stretch [59]. After GO reduction to rGO, the peak of oxygen-containing groups (O-H, C=O, and C-O) were weakened or disappeared, which suggested that oxygenic groups were eliminated (as seen in Figure 13(r)) [60].

Figure 13 FTIR spectra of (u) graphite, (s) GO, and (r) rGO

#### 5.1.1.4 Morphological features

The SEM image shows the morphology of graphite, GO, and rGO as seen in Figure 14. Figure 14(a) shows the layers of graphite that were stacked. As shown in Figure 14(b)-(c), GO and rGO possessed rough and flaky texture and each sheet was separated from one another. As GO and rGO appeared similar in morphology, energy dispersive X-ray spectroscopy (EDX) was used to study different elements on the surface. The atomic composition from SEM-EDX analysis of graphite, GO and rGO was listed in Table 4, The GO contained more oxygen atoms compared to graphite. The rGO contained fewer oxygen atoms compared to GO because oxygen-containing functional groups were removed from the structure during the reduction of GO to rGO. The SEM-EDX results suggested a successful rGO synthesis.

Figure 14 SEM images (magnification: 6k) of (a) graphite, (b) GO, and (c) rGO

Table 4 Summarization of each atomic surface from SEM-EDX analysis of graphite, GO, and rGO

Sample	%C	%O
graphite	99.12	0.88
GO	67.22	32.78
rGO	89.94	10.14

## 5.1.2 Adsorption of methylene blue on rGO

### 5.1.2.1 The adsorption of methylene blue in the dark

Figure 15 shows the adsorption of methylene blue in the dark. The solution was stirred continuously for 4 hours to determine the time required for adsorption equilibrium. The result indicated that after 1 hour, the adsorption of methylene blue reached a steady level. Therefore, the period of adsorption equilibrium in this experiment was chosen as 1 hour.

Figure 15 Adsorption of methylene blue in the absence of light using rGO

## CHAPTER 5.2

### RESULTS AND DISCUSSION

#### OF VARYING THE AMOUNT OF RGO IN THE CATALYSTS

The results and discussion in chapter 5.2 investigated the effects of different amount of rGO in TiO<sub>2</sub>/rGO catalysts. In the synthesis of TiO<sub>2</sub>/rGO catalysts, APTMS-TiO<sub>2</sub> (22.1 mmol) was synthesized with the same amount as the research relevant [44]. This chapter are divided into two major parts. In the first part, several characterization techniques for the TiO<sub>2</sub> and TiO<sub>2</sub>/rGO catalysts including UV-vis, PL, FTIR, XRD, N<sub>2</sub> physisorption and SEM are described. And in the second part, the photocatalytic performance degradation of methylene blue under UV and visible irradiation are discussed.

#### 5.2.1 Characterization of the TiO<sub>2</sub> and TiO<sub>2</sub>/rGO catalysts

##### 5.2.1.1 Optical absorption properties

To compare the optical absorption properties of TiO<sub>2</sub> and TiO<sub>2</sub>/rGO catalysts that contained different amounts of rGO, the samples were analyzed by UV-visible spectroscopy in the wavelength range of 200-800 nm. As shown in Figure 16(p), TiO<sub>2</sub> exhibited strong absorption in the UV region (200-400 nm), but very weak absorption in the visible region (400-700 nm). Figure 16(a)-(g) shows that when APTMS-TiO<sub>2</sub> (22.1mmol) was wrapped with rGO, the light absorption in the visible region was enhanced. TiO<sub>2</sub>/rGO catalysts exhibited better absorption properties in the visible region than TiO<sub>2</sub> and APTMS-TiO<sub>2</sub> did because rGO contained -C=C- bonds, a chromophore, that showed good absorption in the UV and visible regions. Therefore, an increase in rGO in the catalyst brought about greater absorption than APTMS-TiO<sub>2</sub> (22.1 mmol) and TiO<sub>2</sub>.

Figure 16 UV-Vis spectra of (p)  $\text{TiO}_2$ , (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (b)  $\text{TiO}_2/\text{rGO}$  (1:0.005), (c)  $\text{TiO}_2/\text{rGO}$  (1:0.01), (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (e)  $\text{TiO}_2/\text{rGO}$  (1:0.03), (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (g)  $\text{TiO}_2/\text{rGO}$  (1:0.05)

Moreover, the bandgap of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts could be calculated from UV-vis spectra (as seen in Appendix F). The bandgap of the  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were estimated from Figure 17 and was listed in Table 5. The bandgap of  $\text{TiO}_2$  is 3.06 eV, similar to the bandgap of  $\text{TiO}_2/\text{rGO}$  (1:0). When rGO was added to APTMS- $\text{TiO}_2$ , the bandgap became slightly narrower because rGO had  $\pi$ -conjugated structure leading to good light absorption. The narrower bandgap resulted in the catalyst that absorbed more light in the visible region and exhibited good photocatalytic activity.

Figure 17 Plot of the bandgap, as derived from the diffuse reflectance UV-Vis spectra of (p)  $\text{TiO}_2$ , (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (b)  $\text{TiO}_2/\text{rGO}$  (1:0.005), (c)  $\text{TiO}_2/\text{rGO}$  (1:0.01), (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (e)  $\text{TiO}_2/\text{rGO}$  (1:0.03), (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (g)  $\text{TiO}_2/\text{rGO}$  (1:0.05)

Table 5 The comparison bandgap from UV-vis spectra of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts

Sample	Bandgap (eV)
$\text{TiO}_2$	3.06
$\text{TiO}_2/\text{rGO}$ (1:0)	3.06
$\text{TiO}_2/\text{rGO}$ (1:0.005)	3.05
$\text{TiO}_2/\text{rGO}$ (1:0.01)	3.02
$\text{TiO}_2/\text{rGO}$ (1:0.02)	2.99
$\text{TiO}_2/\text{rGO}$ (1:0.03)	2.93
$\text{TiO}_2/\text{rGO}$ (1:0.04)	2.89
$\text{TiO}_2/\text{rGO}$ (1:0.05)	2.92

### 5.2.1.2 Photoluminescence measurement

Photoluminescence (PL) was employed to investigate the efficiency of charge carrier trapping, immigration and transfer of the photogenerated electrons and holes in photocatalyst. The PL spectra of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were measured in the wavelength from 375 nm to 550 nm under 325 nm light excitation (as seen in Figure 18). Broad emission band of  $\text{TiO}_2/\text{rGO}$  catalysts were smaller than that of  $\text{TiO}_2$ . With the increasing amount of rGO, the emission intensity gradually weakened.  $\text{TiO}_2/\text{rGO}$  (1:0.04) exhibited the lowest emission intensity. Therefore, the photogenerated electrons of  $\text{TiO}_2$  were effectively transferred to rGO with slower recombination rate, thereby generating more activated  $\cdot\text{OH}$  for methylene blue degradation. The rGO was added to catalyst in order to decrease the electrons-holes recombination because of its excellent electron transportation properties. Consequently, lower electron-hole recombination endowed the  $\text{TiO}_2/\text{rGO}$  catalyst with high photocatalytic activity.

Figure 18 PL spectra of (p)  $\text{TiO}_2$ , (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (b)  $\text{TiO}_2/\text{rGO}$  (1:0.005), (c)  $\text{TiO}_2/\text{rGO}$  (1:0.01), (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (e)  $\text{TiO}_2/\text{rGO}$  (1:0.03), (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (g)  $\text{TiO}_2/\text{rGO}$  (1:0.05)

### 5.2.1.3 FTIR analysis

The FTIR spectra of  $\text{TiO}_2$ , APTMS- $\text{TiO}_2$  (22.1 mmol) and  $\text{TiO}_2/\text{rGO}$  catalysts were investigated by Fourier transform infrared spectroscopy with a transmittance mode (As seen in Figure 19). The strong band in the wavenumber range of  $550\text{--}900\text{ cm}^{-1}$  was assigned to Ti-O-Ti stretching vibration [10] and was observed in every sample. After  $\text{TiO}_2$  surface was modified with APTMS, small peaks at  $1017\text{ cm}^{-1}$  and  $1100\text{ cm}^{-1}$  were detected, were attributed to the stretching vibrations of Si-O-Ti and Si-O-Si, respectively [61]. This signal was a result of a chemical interaction between  $\text{TiO}_2$  and APTMS on the surface of modified  $\text{TiO}_2$ . When rGO was added to the APTMS- $\text{TiO}_2$ , the peak at  $1017\text{ cm}^{-1}$  and  $1100\text{ cm}^{-1}$  became smaller. This result suggested that the rGO sheets were wrapped around APTMS- $\text{TiO}_2$  particles.

**Figure 19** FTIR spectra of (p)  $\text{TiO}_2$ , (l) APTMS- $\text{TiO}_2$  (22.1 mmol), (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (b)  $\text{TiO}_2/\text{rGO}$  (1:0.005), (c)  $\text{TiO}_2/\text{rGO}$  (1:0.01), (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (e)  $\text{TiO}_2/\text{rGO}$  (1:0.03), (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (g)  $\text{TiO}_2/\text{rGO}$  (1:0.05)

#### 5.2.1.4 Phase structure

The phase structures of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were characterized using X-ray diffractometry (XRD). In Figure 20, the diffraction peaks at  $2\theta$  of  $25.4^\circ$ ,  $37.8^\circ$ ,  $47.8^\circ$ ,  $54.4^\circ$ ,  $68.8^\circ$ , and  $75.2^\circ$  were assigned to the anatase phase. The peaks at  $2\theta$  of  $27.4^\circ$ ,  $36.1^\circ$ ,  $41.2^\circ$ , and  $62.8^\circ$  corresponded to rutile phase and a small peak at  $2\theta$  of  $30.7^\circ$  was assigned to brookite phase. Moreover, the XRD pattern of  $\text{TiO}_2/\text{rGO}$  catalysts was similar to  $\text{TiO}_2$  and the diffraction peak of rGO was not detected.

The crystallite sizes of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalyst were calculated by Debye-Scherrer equation (in Appendix D). Table 6 listed the crystallite size of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts. The crystallite sizes of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were almost unchanged (7.4 -7 . 9 nm) because  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  were calcined only once at the same temperature.

The phase composition of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts was displayed in Table 6. The calculation of phase composition was shown in Appendix E.  $\text{TiO}_2$  consisted of 72% anatase, 17% rutile, and 11% brookite. After  $\text{TiO}_2$  was wrapped with rGO, the composition of anatase phase was slightly reduced and the composition of rutile phase was slightly increased because anatase phase transformed to rutile phase when being heated during the reflux process [6].

Figure 20 XRD patterns of (p)  $\text{TiO}_2$ , (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (b)  $\text{TiO}_2/\text{rGO}$  (1:0.005), (c)  $\text{TiO}_2/\text{rGO}$  (1:0.01), (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (e)  $\text{TiO}_2/\text{rGO}$  (1:0.03), (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (g)  $\text{TiO}_2/\text{rGO}$  (1:0.05)

Table 6 Crystallite size and phase composition of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts

Sample	Crystallite size (nm)	Phase composition (%)		
		Anatase	Rutile	Brookite
$\text{TiO}_2$	7.7	72	17	11
$\text{TiO}_2/\text{rGO}$ (1:0)	7.8	67	22	11
$\text{TiO}_2/\text{rGO}$ (1:0.005)	7.8	65	21	14
$\text{TiO}_2/\text{rGO}$ (1:0.01)	7.9	64	22	13
$\text{TiO}_2/\text{rGO}$ (1:0.02)	7.9	65	22	13
$\text{TiO}_2/\text{rGO}$ (1:0.03)	7.6	70	17	13
$\text{TiO}_2/\text{rGO}$ (1:0.04)	7.9	67	19	14
$\text{TiO}_2/\text{rGO}$ (1:0.05)	7.4	67	20	14

### 5.2.1.5 Measurement of specific surface area

The specific surface areas of TiO<sub>2</sub>, rGO, and TiO<sub>2</sub>/rGO catalysts are listed in Table 7. TiO<sub>2</sub> had a specific surface area of 108.2 m<sup>2</sup>/g. When rGO was added to TiO<sub>2</sub>/rGO catalysts, the surface area of TiO<sub>2</sub>/rGO catalysts increased to 104.9-119.3 m<sup>2</sup>/g. An increase in specific surface areas came from rGO that had has a high specific surface area (295.9 m<sup>2</sup>/g).

**Table 7** Surface area of TiO<sub>2</sub>, rGO, and TiO<sub>2</sub>/rGO catalysts

Sample	Surface area (m <sup>2</sup> /g)
TiO <sub>2</sub>	108.2
rGO	295.9
TiO <sub>2</sub> /rGO (1:0)	94.4
TiO <sub>2</sub> /rGO (1:0.005)	104.9
TiO <sub>2</sub> /rGO (1:0.01)	107.2
TiO <sub>2</sub> /rGO (1:0.02)	109.5
TiO <sub>2</sub> /rGO (1:0.03)	114.8
TiO <sub>2</sub> /rGO (1:0.04)	119.3
TiO <sub>2</sub> /rGO (1:0.05)	116.2

### 5.2.1.6 Morphological features

The SEM images were used to confirm that rGO wrapped around the surface of APTMS-TiO<sub>2</sub> (22.1 mmol). The morphology of rGO, APTMS-TiO<sub>2</sub> (22.1 mmol), and TiO<sub>2</sub>/rGO catalyst were displayed in Figure 21. The rGO sheets possessed rough and corrugated texture (see Figure 21(a)). From Figure 21(b), one saw TiO<sub>2</sub> spherical particles. After APTMS modification, the morphology of APTMS-TiO<sub>2</sub> was similar to that of TiO<sub>2</sub> as shown in Figure 21(c). Figure 21(d) displayed a group of TiO<sub>2</sub> spherical particles that are wrapped with rGO sheets, suggesting the successful wrapping of rGO.

**Figure 21** SEM image (magnification: 6k) of (a) rGO

## 5.2.2 Photocatalytic performance

The photocatalytic performance of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were evaluated in photocatalytic degradation of methylene blue under UV and visible light irradiations. The catalyst was put in a methylene blue solution and the mixture was stirred constantly in the dark for 1 hour to achieve adsorption equilibrium. After that, the mixture was exposed to either UV or visible light for 3 hours. The sample was collected every 15 minutes to determine the conversion of methylene blue in the photocatalytic reaction.

### 5.2.2.1 The degradation under UV light irradiation over $\text{TiO}_2$ and $\text{TiO}_2/\text{rGO}$ catalysts

The photocatalytic activities of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were investigated for the degradation of methylene blue under UV irradiation as shown in Figure 22. In Table 8, the experiment without catalyst produced the lowest conversion. At the beginning of the experiment ( $t=0$ ), The initial concentration of methylene blue in the solution that contained  $\text{TiO}_2/\text{rGO}$  catalysts were lower than that with  $\text{TiO}_2$  because the higher specific surface area of  $\text{TiO}_2/\text{rGO}$  catalysts possibly adsorbed more dye. An increasing amount of rGO in the catalyst produced higher conversion of methylene blue than  $\text{TiO}_2$  did. Thus, addition of rGO enhanced the photocatalytic activity. The highest conversion was observed for  $\text{TiO}_2/\text{rGO}$  (1:0.04) because of the reduced electron-hole recombination (see Figure 18), and better visible light absorption (see Figure 16).

Figure 22 Photocatalytic degradation of methylene blue result under UV light irradiations using (o) no catalyst, (p) TiO<sub>2</sub>, (a) TiO<sub>2</sub>/rGO (1:0), (b) TiO<sub>2</sub>/rGO (1:0.005), (c) TiO<sub>2</sub>/rGO (1:0.01), (d) TiO<sub>2</sub>/rGO (1:0.02), (e) TiO<sub>2</sub>/rGO (1:0.03), (f) TiO<sub>2</sub>/rGO (1:0.04), and (g) TiO<sub>2</sub>/rGO (1:0.05)

**Table 8** The conversion of methylene blue degradation after 3 hours of UV light exposure over  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts

Sample	Conversion
no catalyst	13.13
$\text{TiO}_2$	45.93
$\text{TiO}_2/\text{rGO}$ (1:0)	50.51
$\text{TiO}_2/\text{rGO}$ (1:0.005)	55.00
$\text{TiO}_2/\text{rGO}$ (1:0.01)	57.17
$\text{TiO}_2/\text{rGO}$ (1:0.02)	62.72
$\text{TiO}_2/\text{rGO}$ (1:0.03)	65.87
$\text{TiO}_2/\text{rGO}$ (1:0.04)	69.47
$\text{TiO}_2/\text{rGO}$ (1:0.05)	67.19

#### 5.2.2.2 The degradation under visible light irradiation over $\text{TiO}_2$ and $\text{TiO}_2/\text{rGO}$ catalysts

The photocatalytic activity of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts were evaluated by the degradation of methylene blue under visible irradiation as seen in Figure 23. The order of increasing photocatalytic activity was  $\text{TiO}_2$ ,  $\text{TiO}_2/\text{rGO}$  (1:0),  $\text{TiO}_2/\text{rGO}$  (1:0.005),  $\text{TiO}_2/\text{rGO}$  (1:0.01),  $\text{TiO}_2/\text{rGO}$  (1:0.02),  $\text{TiO}_2/\text{rGO}$  (1:0.03),  $\text{TiO}_2/\text{rGO}$  (1:0.05) and  $\text{TiO}_2/\text{rGO}$  (1:0.04). This same trend was observed in the results of PL, UV-vis, and bandgap values. Similar to the experiments under UV irradiation, the highest conversion was observed for  $\text{TiO}_2/\text{rGO}$  (1:0.04) (see Table 9). The optimum value of rGO content in APTMS- $\text{TiO}_2$  for degradation of methylene blue is 4 %wt. Obviously, the photocatalytic activity of the catalyst under UV irradiation was higher than that of the catalyst under visible irradiation because UV irradiation consisted of photon with higher energy than visible irradiation did, leading to generation of more  $\bullet\text{OH}$ , which decomposed methylene blue.

Figure 23 Photocatalytic degradation of methylene blue result under visible light irradiations using (o) no catalyst, (p) TiO<sub>2</sub>, (a) TiO<sub>2</sub>/rGO (1:0), (a) TiO<sub>2</sub>/rGO (1:0), (b) TiO<sub>2</sub>/rGO (1:0.005), (c) TiO<sub>2</sub>/rGO (1:0.01), (d) TiO<sub>2</sub>/rGO (1:0.02), (e) TiO<sub>2</sub>/rGO (1:0.03), (f) TiO<sub>2</sub>/rGO (1:0.04), and (g) TiO<sub>2</sub>/rGO (1:0.05)

**Table 9** The conversion of methylene blue degradation under visible light over  $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}$  catalysts

Sample	Conversion
no catalyst	8.31
$\text{TiO}_2$	17.47
$\text{TiO}_2/\text{rGO}$ (1:0)	19.87
$\text{TiO}_2/\text{rGO}$ (1:0.005)	22.13
$\text{TiO}_2/\text{rGO}$ (1:0.01)	23.96
$\text{TiO}_2/\text{rGO}$ (1:0.02)	25.23
$\text{TiO}_2/\text{rGO}$ (1:0.03)	27.67
$\text{TiO}_2/\text{rGO}$ (1:0.04)	29.96
$\text{TiO}_2/\text{rGO}$ (1:0.05)	28.91

**CHAPTER 5.3**  
**RESULTS AND DISCUSSION**  
**OF SURFACE MODIFICATION OF CATALYSTS**  
**WITH AMOUNT OF APTMS**

The results and discussion in chapter 5.3 investigated the effect of varying the amount of APTMS between 2.21 and 22.1 mmol in catalyst. In the surface modification of  $\text{TiO}_2$  with APTMS, the amount of APTMS was reduced from 22.1 mmol to 2.21 mmol because the thin layer of APTMS exhibited higher photocatalytic activity than the thick layer of APTMS [35].  $\text{TiO}_2/\text{rGO}$  catalysts were synthesized from APTMS- $\text{TiO}_2$  (22.1 mmol) and were wrapped with rGO, while  $\text{TiO}_2/\text{rGO}^*$  catalysts were synthesized from APTMS- $\text{TiO}_2$  (2.21 mmol) and were wrapped with rGO. This chapter are divided into two major parts. In the first part, the results from several characterization techniques for the  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts including UV-vis, PL, FTIR, XRD,  $\text{N}_2$  physisorption, and SEM are described. And in the second part, the photocatalytic degradation of methylene blue in UV and visible irradiation was discussed. This chapter we selected the amount of rGO in the catalyst to be 0, 0.02, and 0.04 g because  $\text{TiO}_2/\text{rGO}$  (1:0.04) gave the best catalytic performance in Chapter 5.2.

**5.3.1 Characterization of the APTMS- $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts**

**5.3.1.1 TGA analysis**

There were three stages of weight loss as seen in Figure 24. The first stage, weight loss below at 120 °C was caused by water elimination from surface and pore. The second stage, weight loss at the range of 120-300 °C corresponded to the removal of chemisorbed hydroxyl group [35]. The last stage, weight loss at the range of 300-550 °C was a result of amine group decomposition [62, 63]. In addition, the weight loss of APTMS- $\text{TiO}_2$  (Figure 24(k)&(l)) was smaller than that of  $\text{TiO}_2$  (Figure 24(p)) in the temperature range of 120-300 °C, indicating that APTMS- $\text{TiO}_2$  had a lower moisture content than  $\text{TiO}_2$  had due to the hydrophobic property of Si-O-Si group [64]. The amine content of APTMS-

TiO<sub>2</sub> (22.1 mmol) was greater than APTMS-TiO<sub>2</sub> (2.21 mmol) so its total weight loss was larger than APTMS-TiO<sub>2</sub> (2.21 mmol). Thus, the total weight loss of 3.82 %wt, 8.35 %wt and 13.38 %wt for TiO<sub>2</sub>, APTMS-TiO<sub>2</sub> (2.21 mmol), and APTMS-TiO<sub>2</sub> (22.1 mmol) respectively.

Figure 24 TGA of (p) TiO<sub>2</sub>, (k) APTMS-TiO<sub>2</sub> (2.21 mmol), and (l) APTMS-TiO<sub>2</sub> (22.1 mmol)

### 5.3.1.2 Optical absorption properties

To compare the optical absorption properties of TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* catalysts, we selected the TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* catalysts that contained the same amount of rGO (see Figure 25). The modification of the surface of TiO<sub>2</sub> with APTMS enhanced the optical absorption properties [65]. TiO<sub>2</sub>/rGO\* catalyst had better absorption than TiO<sub>2</sub>/rGO catalyst had because the thin layer of N and Si from APTMS on TiO<sub>2</sub> surface was better at promoting the absorption than thick layer of N and Si [66-69]. Therefore, reducing the amount of APTMS gave rise to better absorption [38].

Figure 25 UV-Vis spectra of (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (h)  $\text{TiO}_2/\text{rGO}$  (1:0)\*, (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (i)  $\text{TiO}_2/\text{rGO}$  (1:0.02)\*, (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (j)  $\text{TiO}_2/\text{rGO}$  (1:0.04)\*

In addition, the bandgap of samples was calculated using the information from Figure 25. The plot in Figure 26 was prepared and the calculated bandgap was listed in Table 10.  $\text{TiO}_2/\text{rGO}^*$  catalyst (modified surface with APTMS 2.21 mmol) possessed slightly smaller bandgap than  $\text{TiO}_2/\text{rGO}$  catalyst (modified surface with APTMS 22.1 mmol) did. The narrow bandgap resulted in electrons moving from the valence band to the conduction band more easily and quickly than the wider bandgap. The N and Si created the intermediate states within  $\text{TiO}_2$  bandgap, leading to narrowing bandgap [67, 68]. Therefore, a thin layer of N and Si on  $\text{TiO}_2$  surface also improved the light absorption [66-69].

**Figure 26** Plot of the bandgap, as derived from the diffuse reflectance UV-Vis spectra of (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (h)  $\text{TiO}_2/\text{rGO}$  (1:0)\*, (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (i)  $\text{TiO}_2/\text{rGO}$  (1:0.02)\*, (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (j)  $\text{TiO}_2/\text{rGO}$  (1:0.04)\*

**Table 10** The comparison bandgap from UV-vis spectra of APTMS- $\text{TiO}_2$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts

Sample	Bandgap (eV)
$\text{TiO}_2/\text{rGO}$ (1:0)	3.06
$\text{TiO}_2/\text{rGO}$ (1:0.02)	2.99
$\text{TiO}_2/\text{rGO}$ (1:0.04)	2.89
$\text{TiO}_2/\text{rGO}$ (1:0)*	3.03
$\text{TiO}_2/\text{rGO}$ (1:0.02)*	2.96
$\text{TiO}_2/\text{rGO}$ (1:0.04)*	2.86

### 5.3.1.3 Photoluminescence measurement

The PL spectra of  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts were compared in Figure 27. The low intensity of PL was ascribed to slower rate of recombination of the charge carriers. The emission band at 375-550 nm was attributed to the emission from the electron-hole recombination. The PL spectra of samples were obtained using an excitation wavelength of 325 nm. As a result, the APTMS- $\text{TiO}_2$  revealed a spectrum with lower intensity than that of  $\text{TiO}_2$  [70]. With the same rGO content,  $\text{TiO}_2/\text{rGO}^*$  catalyst (using APTMS 2.21 mmol) exhibited lower emission intensity than  $\text{TiO}_2/\text{rGO}$  catalyst (using APTMS 22.1 mmol). This is an evidence that the thin layer of N and Si coverage on  $\text{TiO}_2$  surface reduced the recombination rate of electron and hole [71, 72]. Hence,  $\text{TiO}_2/\text{rGO}^*$  catalyst can slightly enhance the photocatalytic activity.

Figure 27 PL spectra of (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (h)  $\text{TiO}_2/\text{rGO}^*$  (1:0)\*, (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (i)  $\text{TiO}_2/\text{rGO}^*$  (1:0.02)\*, (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (j)  $\text{TiO}_2/\text{rGO}^*$  (1:0.04)\*

### 5.3.1.4 FTIR analysis

The FTIR spectra of APTMS-TiO<sub>2</sub> (2.21 mmol), APTMS-TiO<sub>2</sub> (22.1 mmol), TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO\* catalysts were displayed in Figure 28. Intensive bands at wavenumbers of 600-710 cm<sup>-1</sup> were clearly observed. These bands were related to the stretching of Ti-O-Ti bonds [10]. After the modification using APTMS 22.1 mmol, two small peaks appeared at 1017 cm<sup>-1</sup> and, 1100 cm<sup>-1</sup>. They were attributed to the vibrations of Si-O-Ti, Si-O-Si [61], But when APTMS 2.21 mmol was used, instead of 22.1 mmol, both peaks became smaller. The Si-O-Ti bond in the APTMS-TiO<sub>2</sub> was created from the reaction between caused by methoxy groups (CH<sub>3</sub>O-R) of APTMS and hydroxyl groups on the TiO<sub>2</sub> surface (Ti-OH). Therefore, varying the amount of APTMS affected the surface properties of TiO<sub>2</sub> (as seen in Figure 28 (l)-(k)). In comparison, FTIR spectra of TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* appeared similar (as seen in Figure 28(a,d,f,h,i,j)).

Figure 28 FTIR spectra of (k) APTMS-TiO<sub>2</sub> (2.21 mmol), (l) APTMS-TiO<sub>2</sub> (22.1 mmol), (a) TiO<sub>2</sub>/rGO (1:0), (d) TiO<sub>2</sub>/rGO (1:0.02), (f) TiO<sub>2</sub>/rGO (1:0.04), (h) TiO<sub>2</sub>/rGO (1:0)\*, (i) TiO<sub>2</sub>/rGO (1:0.02)\*, and (j) TiO<sub>2</sub>/rGO (1:0.04)\*

### 5.3.1.5 Phase structure

The phase structure of APTMS-TiO<sub>2</sub>, TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO\* catalysts were determined from XRD results (see in Figure 29). The XRD peaks detected at  $2\theta$  of 25.4°, 37.8°, 47.8°, 54.4°, 68.8°, and 75.2° corresponded to anatase phase. The diffraction peaks at  $2\theta$  of 27.4°, 36.1°, 41.2°, and 62.8° were assigned to rutile phase and brookite phase occurred at  $2\theta$  of 30.7°. The XRD patterns of APTMS-TiO<sub>2</sub> (2.21 mmol), TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO\* catalysts appeared similar. In Figure 29(l), the excessive amount of amine coating on TiO<sub>2</sub> lowered the diffraction peak intensity. APTMS-TiO<sub>2</sub> (22.1 mmol) was wrapped with rGO through the similar reflux process, resulting in the intensity of TiO<sub>2</sub>/rGO in XRD pattern resembling the intensity of TiO<sub>2</sub>/rGO\* in XRD pattern [10, 73] because some APTMS was removed during the reflux process [45].

Calculation of crystallites size was demonstrated in Appendix D. The crystallites size of APTMS-TiO<sub>2</sub>, TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO\* catalysts were in the range 7.6-7.9 nm as seen in Table 11. A change in crystallite size was hardly detectable because the temperature of the reflux process during rGO wrapping was too low to give rise to the sintering of TiO<sub>2</sub> [74].

Determination of phase composition was shown in Appendix E. Table 11 shows the phase composition of the APTMS-TiO<sub>2</sub>, TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO\* catalysts. When comparing the phase composition among the catalysts, the phase composition of APTMS-TiO<sub>2</sub>, TiO<sub>2</sub>/rGO, and TiO<sub>2</sub>/rGO catalysts did not change that much because they underwent the same process.

Figure 29 XRD patterns of (k) APTMS-TiO<sub>2</sub> (2.21 mmol), (l) APTMS-TiO<sub>2</sub> (22.1 mmol), (a) TiO<sub>2</sub>/rGO (1:0), (d) TiO<sub>2</sub>/rGO (1:0.02), (f) TiO<sub>2</sub>/rGO (1:0.04), (h) TiO<sub>2</sub>/rGO (1:0)\*, (i) TiO<sub>2</sub>/rGO (1:0.02)\*, and (j) TiO<sub>2</sub>/rGO (1:0.04)\*

Table 11 Crystallite size and Phase composition of APTMS-TiO<sub>2</sub>, TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* catalysts

Sample	Crystallite size (nm)	Phase composition (%)		
		Anatase	Rutile	Brookite
APTMS-TiO <sub>2</sub> (2.21 mmol)	7.8	70	19	10
APTMS-TiO <sub>2</sub> (22.1 mmol)	7.5	66	20	14
TiO <sub>2</sub> /rGO (1:0)	7.8	67	22	11
TiO <sub>2</sub> /rGO (1:0.02)	7.9	65	22	13
TiO <sub>2</sub> /rGO (1:0.04)	7.9	67	19	14
TiO <sub>2</sub> /rGO (1:0)*	7.6	67	22	11
TiO <sub>2</sub> /rGO (1:0.02)*	7.8	69	20	11
TiO <sub>2</sub> /rGO (1:0.04)*	7.6	69	19	11

### 5.3.1.6 Measurement of specific surface area

The specific surface areas of  $\text{TiO}_2$ , APTMS- $\text{TiO}_2$ ,  $\text{TiO}_2/\text{rGO}$ , and  $\text{TiO}_2/\text{rGO}^*$  catalysts along with the pore volumes of  $\text{TiO}_2$ , APTMS- $\text{TiO}_2$  are listed in Table 12. After modifying  $\text{TiO}_2$  surface with APTMS, the specific surface area and pore volume of the APTMS- $\text{TiO}_2$  dropped significantly, because APTMS entered the pore of  $\text{TiO}_2$ , leading to pore blockage [62]. This result was evidenced by the decrease in pore volume with an increasing amine content. From Table 12,  $\text{TiO}_2/\text{rGO}^*$  catalyst possessed a larger surface area than  $\text{TiO}_2/\text{rGO}$  catalyst did because  $\text{TiO}_2/\text{rGO}^*$  catalyst employed APTMS 2.21 mmol 10 times lower than that used in  $\text{TiO}_2/\text{rGO}$  catalyst, causing less pore blockage.

**Table 12** Specific surface areas of  $\text{TiO}_2$ , APTMS- $\text{TiO}_2$ ,  $\text{TiO}_2/\text{rGO}$ , and  $\text{TiO}_2/\text{rGO}^*$  catalysts and pore volumes of  $\text{TiO}_2$ , and APTMS- $\text{TiO}_2$

Sample	Surface area ( $\text{m}^2/\text{g}$ )	Pore volume ( $\text{cm}^3/\text{g}$ )
$\text{TiO}_2$	108.2	0.248
APTMS- $\text{TiO}_2$ (2.21 mmol)	89.1	0.147
APTMS- $\text{TiO}_2$ (22.1 mmol)	28.5	0.034
$\text{TiO}_2/\text{rGO}$ (1:0)	94.4	-
$\text{TiO}_2/\text{rGO}$ (1:0.02)	109.5	-
$\text{TiO}_2/\text{rGO}$ (1:0.04)	119.3	-
$\text{TiO}_2/\text{rGO}$ (1:0)*	105.8	-
$\text{TiO}_2/\text{rGO}$ (1:0.02)*	116.3	-
$\text{TiO}_2/\text{rGO}$ (1:0.04)*	124.7	-

### 5.3.1.7 Morphological features

The SEM images shows the morphology of the catalysts that was modified with a different amount of APTMS (see Figure 30). Figures 30 (a) and (b) displayed the morphology of  $\text{TiO}_2$  surface modified using 2.21 and 22.1 mmol of APTMS, respectively.

The morphology of APTMS-TiO<sub>2</sub> (2.21 mmol) and APTMS-TiO<sub>2</sub> (22.1 mmol) appeared similarly as spherical particles. Modified surface of TiO<sub>2</sub> with APTMS was not changing the morphology. Figure 30 (c) and (d) showed the APTMS-TiO<sub>2</sub> catalysts that were wrapped with rGO. Both of them also looked similar.

Figure 30 SEM images (magnification: 40k) of (a) APTMS-TiO<sub>2</sub> (2.21 mmol), (b) APTMS-TiO<sub>2</sub> (22.1 mmol) and SEM images (magnification: 100k) of (c) TiO<sub>2</sub>/rGO (1:0.04)\*, (d) TiO<sub>2</sub>/rGO (1:0.04)

### 5.3.2 Photocatalytic performance

To assess the photocatalytic activities of the TiO<sub>2</sub>/rGO and TiO<sub>2</sub>/rGO\* catalyst, we investigate the degradation of methylene blue. The system was stirred constantly and was kept in the dark for 1 hour to attain adsorption equilibrium. UV or visible light bulbs were turned on for 3 hours after that and sample was collected every 15 minutes. The concentration of the methylene blue was measured by a UV-Vis spectrophotometer.

### 5.3.2.1 The degradation under UV light irradiation over $\text{TiO}_2/\text{rGO}$ and $\text{TiO}_2/\text{rGO}^*$ catalysts

Figure 31 showed the photocatalytic activity of  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts for the degradation of methylene blue under UV irradiation. When APTMS content was reduced, the conversion of photocatalytic degradation was slightly increased (as seen in Table 13). The order of increasing photocatalytic activities of the catalysts under UV irradiation was  $\text{TiO}_2/\text{rGO}$  (1:0),  $\text{TiO}_2/\text{rGO}$  (1:0)\*,  $\text{TiO}_2/\text{rGO}$  (1:0.02),  $\text{TiO}_2/\text{rGO}$  (1:0.02)\*,  $\text{TiO}_2/\text{rGO}$  (1:0.04) and  $\text{TiO}_2/\text{rGO}$  (1:0.04)\*, respectively. These results were consistent with decline in photoluminescence signals (see Figure 27), better visible light absorption (see Figure 25), and narrowing bandgap (see Figure 26). The results of methylene blue degradation using catalysts under UV light was greater photocatalytic activities than visible lights because UV light comprised photons with higher energy than visible light. As a result, modifying the surface of  $\text{TiO}_2$  with APTMS (2.21 mmol) exhibited higher photocatalytic activity than modifying the surface of  $\text{TiO}_2$  with APTMS (22.1 mmol). Therefore,  $\text{TiO}_2/\text{rGO}$  (1:0.04)\* catalyst exhibited the best performance among all samples.

Figure 31 Photocatalytic degradation of methylene blue result under UV light of (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (h)  $\text{TiO}_2/\text{rGO}$  (1:0)\*, (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (i)  $\text{TiO}_2/\text{rGO}$  (1:0.02)\*, (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (j)  $\text{TiO}_2/\text{rGO}$  (1:0.04)\*

Table 13 The conversion of methylene blue degradation under UV light over  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts

Sample	Conversion
no catalyst	13.13
$\text{TiO}_2$	45.93
$\text{TiO}_2/\text{rGO}$ (1:0)	50.51
$\text{TiO}_2/\text{rGO}$ (1:0.02)	62.72
$\text{TiO}_2/\text{rGO}$ (1:0.04)	69.47
$\text{TiO}_2/\text{rGO}$ (1:0)*	52.85
$\text{TiO}_2/\text{rGO}$ (1:0.02)*	64.45
$\text{TiO}_2/\text{rGO}$ (1:0.04)*	70.63

### 5.3.2.2 The degradation under visible light irradiation over $\text{TiO}_2/\text{rGO}$ and $\text{TiO}_2/\text{rGO}^*$ catalysts

Figure 32 displayed the photocatalytic activity of  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts for the degradation of methylene blue under visible irradiation. This result indicated that modified the surface of  $\text{TiO}_2$  with APTMS (2.21 mmol) gave exhibited higher photocatalytic activity than modifying the surface of  $\text{TiO}_2$  with APTMS (22.1 mmol). The conversion of methylene degradation was listed in Table 14. It can be seen that  $\text{TiO}_2/\text{rGO}$  (1:0.04)\* showed the highest conversion than among all samples. The sequence of photocatalytic activity was consistent with results with decline in photoluminescence signals (see Figure 27), better visible light absorption (see Figure 25), and narrowing bandgap (see Figure 26). However, the photodegradation of methylene blue under visible light was lower conversion than that of the catalyst under UV irradiation because visible irradiation consisted of photon with lower energy than UV irradiation did so electrons in the valence band were less excited to the conduction band, resulting in less  $\bullet\text{OH}$ .

Figure 32 Photocatalytic degradation of methylene blue result under visible light of (a)  $\text{TiO}_2/\text{rGO}$  (1:0), (h)  $\text{TiO}_2/\text{rGO}$  (1:0)\*, (d)  $\text{TiO}_2/\text{rGO}$  (1:0.02), (i)  $\text{TiO}_2/\text{rGO}$  (1:0.02)\*, (f)  $\text{TiO}_2/\text{rGO}$  (1:0.04), and (j)  $\text{TiO}_2/\text{rGO}$  (1:0.04)\*

Table 14 The conversion of methylene blue degradation under visible light over  $\text{TiO}_2/\text{rGO}$  and  $\text{TiO}_2/\text{rGO}^*$  catalysts

Sample	Conversion
no catalyst	8.31
$\text{TiO}_2$	17.47
$\text{TiO}_2/\text{rGO}$ (1:0)	19.87
$\text{TiO}_2/\text{rGO}$ (1:0.02)	25.23
$\text{TiO}_2/\text{rGO}$ (1:0.04)	29.96
$\text{TiO}_2/\text{rGO}$ (1:0)*	21.25
$\text{TiO}_2/\text{rGO}$ (1:0.02)*	26.79
$\text{TiO}_2/\text{rGO}$ (1:0.04)*	31.06

## CHAPTER 6

### CONCLUSIONS AND SUGGESTTION

This chapter is divided into two parts. The first part provides the conclusions obtained from the experimental results, and the second part presents the suggestion for the future work.

#### 6.1 Conclusion

##### 6.1.1 Synthesis of graphene oxide and reduced graphene oxide

GO was successfully synthesized by a modified Hummers method, and rGO was prepared from GO via reduction by hydrazine and ammonia.

##### 6.1.2 Varying the amount of rGO in the catalysts

The  $\text{TiO}_2/\text{rGO}$  catalyst was successfully synthesized. The addition of rGO promoted electron transfer and retarded electron-hole recombination. Therefore, the photocatalytic activity of  $\text{TiO}_2/\text{rGO}$  was enhanced. The optimum loading of rGO was 4 %wt in APTMS- $\text{TiO}_2$  (22.1 mmol) and its photocatalytic activity was the highest under both UV and visible light irradiations.

##### 6.1.3 Surface modification of catalyst with varying amount of APTMS

$\text{TiO}_2/\text{rGO}^*$  catalyst was investigated for degradation of methylene blue under UV and visible irradiation. The surface modification of  $\text{TiO}_2$  with APTMS 2.21 mmol yielded a higher photocatalytic than the surface modification with APTMS 22.1 mmol.  $\text{TiO}_2/\text{rGO}$  (1:0.04)\* catalyst exhibited higher photocatalytic activity than  $\text{TiO}_2/\text{rGO}$  (1:0.04) did because the thin layer of N and Si on  $\text{TiO}_2$  surface created the intermediate state within  $\text{TiO}_2$  bandgap, resulting in narrower bandgap and slower recombination rate.

## 6.2 Suggestion

1. Employ another reducing agent or thermal reduction to prepare rGO.
2. Use another coupling agent to modify the surface of  $\text{TiO}_2$ .
3. Investigate the photodegradation using catalysts in packed bed photoreactor.

## APPENDIX A

### CALIBRATION CURVE OF METHYLENE BLUE

The calibration curve of methylene blue used for calculation concentration of methylene blue in photodegradation of methylene blue. The concentration of methylene blue was investigated at 0, 0.5, 2, 4, 6, 8, 10, and 12, respectively (shown in Figure 33).

Figure 33 The calibration curve of methylene blue from UV-vis spectrophotometer (Perkin-Elmer lambda 650)

## APPENDIX B

### LIGHTING INSTRUMENT

Both UV and visible bulbs were used as a light source in methylene blue degradation reaction. Measure the intensity of light by the light sensor (IL 1700 research radiometer), as shown in the Table 15

Table 15 properties of the light blub

Type of light	Brand	Power (W)	Wavelength (nm)	Intensity by sensor UV light (%)	Intensity by sensor visible light (%)
UVC light	Philip	75	200-280	99.69	0.31
Visible light (Daylight)	Philip	18	400-700	1.01	98.99

**APPENDIX B**  
**THE PHOTOCATALYTIC REACTOR DESIGNED**  
**FOR METHYLENE BLUE DEGRADATION**

Cabinet was designed for use in photocatalytic reactions, cabinet is 400 cm wide, 400 cm long and 1000 cm high. The cabinet can be opened in 2 positions: the top for collecting methylene blue solution and the front for set up the experimental. The inside of the cabinet was attached to the aluminium foil sheet to reflect light. The slat was drilled to allow the wires to be placed outside. The two 200 V fan was installed on the right side of cabinets for cooling (as seen in Figure 34).

Figure 34 Cabinet design

Double jacketed reactor was designed for use in photocatalytic reactions, it is a double layer of glass cylinder. The inner cylinder has a radius of 3 cm, 32 cm high and the outer cylinder has a radius of 6 cm, 30 cm high. The space between the bottom of the inner cylinder and the outer cylinder is 1.5 cm (as seen in Figure 35).

The inner cylinder was designed to fit the light bulb. The outer cylinder was designed to contain methylene blue solution. The pipes connected to the outer cylinder, designed to pour methylene blue. The space between the inner cylinder and outer cylinder was designed to insert a magnetic bar.

Figure 35 Double jacketed reactor design

## APPENDIX D

### CALCULATION OF THE CRYSTALLITE SIZE

The crystallite size of  $\text{TiO}_2$  was calculated by combining the Debye-Scherer equation (Equations (10)) and Warren formula (Equations (11) to (12))

Debye-Scherer equation:

$$D = \frac{k\lambda}{\beta \cos\theta} \quad (10)$$

Where

$D$  = Crystallite size ( $\text{\AA}$ )

$k$  = Crystallite-shape factor (0.9)

$\lambda$  = X-ray wavelength ( $1.5418 \text{ \AA}$  for  $\text{CuK}\alpha$ )

$\beta$  = X-ray diffraction broadening (radian)

$\theta$  = Observed peak angle (degree)

The X-ray diffraction broadening ( $\beta$ ) can be obtained by using the Warren formula.

Warren formula:

$$\beta^2 = \beta_M^2 - \beta_S^2 \quad (11)$$

$$\beta = \sqrt{\beta_M^2 - \beta_S^2} \quad (12)$$

Where

$\beta_M$  = Measured peak width in radians at half peak height

$\beta_S$  = Corresponding width of a standard material

**Example:** Calculation of the crystallite size of pure TiO<sub>2</sub> calcined at 400 °C for 2 hours

Finding the half-weight width (101) diffraction peak at 25.4° from the XRD pattern

$$\begin{aligned} \text{The half-weight width (101) diffraction peak} &= 1.06^\circ \\ &= \frac{2\pi \times 1.06}{360} \\ &= 0.0185 \text{ radian} \end{aligned}$$

The corresponding half-height width of peak of  $\alpha$ -alumina = 0.0038 radian

$$\begin{aligned} \text{The broadening} \quad \beta &= \sqrt{\beta_M^2 - \beta_S^2} \\ &= \sqrt{0.0185^2 - 0.0038^2} \\ \beta &= 0.0181 \text{ radian} \end{aligned}$$

$$2\theta = 25.4^\circ$$

$$\theta = 12.7^\circ$$

$$\lambda = 1.54 \text{ \AA}$$

$$\begin{aligned} \text{The crystallite size} \quad D &= \frac{k\lambda}{\beta \cos\theta} \\ &= \frac{(0.9)(1.54)}{(0.0181)\cos(12.7)} \\ &= 77.26 \text{ \AA} \quad = 7.73 \text{ nm} \end{aligned}$$

APPENDIX E  
CALCULATION OF WEIGHT FRACTION OF ANATASE, RUTILE AND  
BROOKITE PHASE OF TiO<sub>2</sub>

Finding  $2\theta$  of TiO<sub>2</sub> can be found from the XRD pattern (as seen in Figure 36), which can divide  $2\theta$  into each phase as shown in the Table 16.

The weight fraction of TiO<sub>2</sub> can be calculated (shown in Equations (13) to (15) below).

$$W_A = \frac{k_A A_A}{k_A A_A + A_R + k_B A_B} \quad (13)$$

$$W_R = \frac{A_R}{k_A A_A + A_R + k_B A_B} \quad (14)$$

$$W_B = \frac{k_B A_B}{k_A A_A + A_R + k_B A_B} \quad (15)$$

Where

$W_A$  = Weight fraction of anatase phase

$W_R$  = Weight fraction of rutile phase

$W_B$  = Weight fraction of brookite phase

$A_A$  = The intensity of the anatase peak

$A_R$  = The intensity of the rutile peak

$A_B$  = The intensity of the brookite peak

$k_A$  = The coefficient factor of anatase (0.886)

$k_B$  = The coefficient factor of brookite (2.721)

Example: Calculation of the phase contents of pure TiO<sub>2</sub> calcined at 400 °C for 2 hours

Figure 36 XRD pattern of pure TiO<sub>2</sub> calcined at 400 °C for 2 hours

Table 16 The 2θ peak of TiO<sub>2</sub> phase by XRD

Phase	2θ
Anatase	25.4
	37.8
	47.8
	54.4
	68.8
	75.2
Rutile	27.4
	36.1
	41.2
	62.8
Brookite	30.7

Calculation of the intensity using the OriginLab program at  $2\theta$  of 25.4, 27.4, and 30.7 were integrated the intensity as follows: 821.12, 27.38, and 88.98 respectively.

$$W_A = \frac{(0.886)(1721.038)}{(0.886)(821.12)+(27.38)+(2.271)(88.98)} = 0.72$$

$$W_R = \frac{(355.6781)}{(0.886)(821.12)+(27.38)+(2.271)(88.98)} = 0.17$$

$$W_B = \frac{(2.271)(88.9822)}{(0.886)(25.4)+(27.38)+(2.271)(88.98)} = 0.11$$

## APPENDIX F

## THE CALCULATION OF THE BANDGAP FROM UV-VIS SPECTRA

From UV-vis spectra can be used to calculate the bandgap of semiconductor material by plotting  $(\alpha hv)^{\frac{1}{n}}$  versus photon energy ( $hv$ ). The photon energy ( $hv$ ) and optical absorption coefficient ( $\alpha$ ) were estimated by equation (16)-(17)

$$hv = E_g = \frac{hc}{\lambda} \quad (16)$$

$$hv = \frac{1240}{\lambda} \quad (17)$$

Where

- $E_g$  = Bandgap of catalyst (eV)  
 $h$  = Plank constant ( $6.62 \times 10^{-34}$  Joules·sec)  
 $c$  = Speed of light ( $3.0 \times 10^8$  meter/sec)  
 $\lambda$  = Wavelength from UV-vis spectra (nm)

Note: 1 eV is  $1.6 \times 10^{-19}$  Joules

$$\alpha = \frac{2.303A}{t} \quad (16)$$

Where

- $\alpha$  = Optical absorption coefficient  
 $A$  = Absorbance  
 $t$  = Thickness of the sample

**Example:** Calculation of the bandgap of  $\text{TiO}_2$

From  $(\alpha h\nu)^{\frac{1}{n}}$ , the power factor (n) is 0.5 because this graph finds direct bandgap.

Figure 37 The bandgap of  $\text{TiO}_2$

From Figure 37, A line cut the X axis presented the bandgap is 3.06 eV.
